<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising: a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 41
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising: a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 41
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising:</p> <p style="padding-left: 20px;">a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 41
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p><u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u></p> <p><u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u></p> <p><u>passing said detected at least a first discrete signal to at least one processor;</u></p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising:</p> <p style="padding-left: 40px;">a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 41
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising: a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 41
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising: a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 41
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> <u>and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising: a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 41
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising: a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 41
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising: a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 41
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

system comprising:

a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 41
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising:</p> <p>a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 41
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising:</p> <p>a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 41
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising: a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 42
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising:</p> <p>a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 42
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising:</p> <p>a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

<p><u>output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 42
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising: a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 42
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u></p> <p><u>delivering said video to a transmitter;</u></p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p><u>transferring said first discrete signal to said transmitter; and</u></p> <p><u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising:</p> <p>a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 42
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising: a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 42
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising: a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>program.</p>
--	-----------------

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 42
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising: a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

least one origination transmitter before a specific time;
and
transmitting from said at least origination
transmitter said first discrete signal and said at least
one control signal.

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 42
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising:</p> <p>a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 42
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p><u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u></p> <p><u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u></p> <p><u>passing said detected at least a first discrete signal to at least one processor;</u></p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising:</p> <p>a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 42
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising: a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 42
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising: a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 42
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> <u>and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising: a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 42
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising: a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 42
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising:</p> <p style="padding-left: 40px;">a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 42
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:
receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;
transferring said at least one discrete signal to a transmitter;
receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;
transferring said one or more control signals to said transmitter; and
transmitting a transmission comprising said at least one discrete signal and said one or more control signals,
wherein said method delivers said video graphic presentation.

varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising:

a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 42
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising:</p> <p>a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 42
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising:</p> <p>a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 42
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>42. A system for processing a television program transmission in which a plurality of types of signal information are transmitted in different patterns, with said types of signal information including at least a unit identification information signal that identifies a unit of information associated with a television program, with said signal types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system capable of processing television programming separately defined from standard analog television, said system comprising:</p> <p style="padding-left: 40px;">a processor for locating or identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 43
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>43. A signal processing system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver;</p> <p>a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program;</p> <p>a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and</p> <p>a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 43
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a</u></p>	<p>43. A signal processing system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver;</p> <p>a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program;</p>

<p><u>second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter;</u></p> <p><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p><u>transferring said at least one control signal to said transmitter; and</u></p> <p><u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	<p>a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and</p> <p>a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>
--	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 43
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p><u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said</u></p>	<p>43. A signal processing system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver;</p> <p>a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program;</p> <p>a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and</p>

<u>instruct signal; and</u> <u>transmitting said at least one control signal from</u> <u>said origination transmitter before a specific time.</u>	a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 43
84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u> <u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u>	43. A signal processing system comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver; a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program; a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 43
93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a</u>	43. A signal processing system comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission;

<p><u>first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</u></p> <p><u>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</u></p> <p><u>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</u></p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver;</p> <p>a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program;</p> <p>a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and</p> <p>a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>
---	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 43
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information</u></p>	<p>43. A signal processing system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver;</p> <p>a processor operatively connected to said decoder for identifying and transferring to a computer an</p>

<p><u>contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program; a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 43
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p>	<p>43. A signal processing system comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver; a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program; a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and a television display device operatively connected to</p>

<u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</u>	said computer for receiving and displaying said portion of the video information content.
---	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 43
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second</u></p>	<p>43. A signal processing system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver;</p> <p>a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program;</p> <p>a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and</p> <p>a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>

<p><u>discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p><u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u></p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 43
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p><u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u></p> <p><u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u></p> <p><u>passing said detected at least a first discrete signal to at least one processor;</u></p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>43. A signal processing system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver;</p> <p>a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program;</p> <p>a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and</p> <p>a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 43
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>43. A signal processing system comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver; a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program; a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 43
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video</u></p>	<p>43. A signal processing system comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver; a processor operatively connected to said decoder</p>

<p><u>presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p><u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u></p> <p><u>transferring said downloadable processor instructions to a transmitter;</u></p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p><u>transferring said one or more control signals to said transmitter; and</u></p> <p><u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	<p>for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program;</p> <p>a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and</p> <p>a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 43
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>43. A signal processing system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver;</p> <p>a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program;</p>

<u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u>	a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.
--	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 43
162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of: receiving a video image at a transmitter station; delivering said video image to a transmitter; receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image; transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u>	43. A signal processing system comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver; a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program; a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 43
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>43. A signal processing system comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver; a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program; a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 43
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p><u>transferring said one or more control signals to said transmitter; and</u></p> <p><u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals.</u></p>	<p>43. A signal processing system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver;</p> <p>a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program;</p> <p>a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and</p> <p>a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>

wherein said method delivers said video graphic presentation.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 43
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at</u></p>	<p>43. A signal processing system comprising:</p> <ul style="list-style-type: none"> a mass medium receiver for receiving a selected broadcast or cablecast transmission; a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver; a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program; a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.

<u>least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u> <u>wherein said method delivers said video graphic presentation.</u>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 43
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one</u></p>	<p>43. A signal processing system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver;</p> <p>a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program;</p> <p>a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and</p> <p>a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>

<u>receiver station,</u> <u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 43
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>43. A signal processing system comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a decoder operatively connected to said mass medium receiver for locating or identifying information in said selected broadcast or cablecast transmission, said information including computer control instructions, said decoder also identifying information that identifies specific programming received by said receiver; a processor operatively connected to said decoder for identifying and transferring to a computer an instruct-to-generate-and-transmit signal that causes said computer to generate and transmit to a television display a portion of the video information content of a television program; a computer operatively connected to said processor and for receiving said instruct-to-generate-and-transmit signal from said processor, said instruct-to-generate-and-transmit signal causing said computer to generate and transmit the portion of the video information content; and a television display device operatively connected to said computer for receiving and displaying said portion of the video information content.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 44
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>44. A television receiver system comprising:</p> <p>a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television program content;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and</p> <p>a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and</p> <p>a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 44
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and</u></p>	<p>44. A television receiver system comprising:</p> <p>a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television program content;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and</p> <p>a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and</p> <p>a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

<p><u>output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 44
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television program content; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 44
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u></p> <p><u>delivering said video to a transmitter;</u></p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p><u>transferring said first discrete signal to said transmitter; and</u></p> <p><u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>44. A television receiver system comprising:</p> <p>a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television program content;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and</p> <p>a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and</p> <p>a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 44
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>44. A television receiver system comprising:</p> <p>a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television program content;</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 44
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television program content; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 44
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television program content; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 44
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;"><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>44. A television receiver system comprising:</p> <p style="padding-left: 20px;">a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display;</p> <p style="padding-left: 20px;">an input device for inputting information of the reaction of a viewer to specific television program content;</p> <p style="padding-left: 20px;">a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and</p> <p style="padding-left: 20px;">a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and</p> <p style="padding-left: 20px;">a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 44
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television program content; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 44
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television program content; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 44
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television program content; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and a television display device operatively connected to said processor for receiving and displaying said video</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	<p>overlay.</p>
---	-----------------

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 44
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> <u>and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television program content; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 44
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television program content; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 44
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display;</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>an input device for inputting information of the reaction of a viewer to specific television program content; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 44
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television program</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

content;

a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and

a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and

a television display device operatively connected to said processor for receiving and displaying said video overlay.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 44
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>44. A television receiver system comprising:</p> <p>a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television program content;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and</p> <p>a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and</p> <p>a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 44
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>44. A television receiver system comprising:</p> <p>a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television program content;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and</p> <p>a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and</p> <p>a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 44
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>44. A television receiver system comprising: a television receiver for receiving a selected broadcast or cablecast television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television program content; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and transferring some of said detected information to a processor; and a processor operatively connected to said detector and said input device for generating and outputting information of a video overlay that is related to said television programming or said reaction information; and a television display device operatively connected to said processor for receiving and displaying said video overlay.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 45
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising:</p> <p>a first mass medium receiver for receiving a broadcast or cablecast transmission;</p> <p>a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions;</p> <p>a transmission operatively connected to said detector for transmitting control instruction to said tuner;</p> <p>a second mass medium receiver for a transmission; and</p> <p>a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 45
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising:</p> <p>a first mass medium receiver for receiving a broadcast or cablecast transmission;</p> <p>a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions;</p> <p>a transmission operatively connected to said detector for transmitting control instruction to said tuner;</p> <p>a second mass medium receiver for a transmission; and</p> <p>a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

<p><u>output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 45
<p>80. <u>A method of delivering a video presentation at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 45
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u></p> <p><u>delivering said video to a transmitter;</u></p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p><u>transferring said first discrete signal to said transmitter; and</u></p> <p><u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising:</p> <p>a first mass medium receiver for receiving a broadcast or cablecast transmission;</p> <p>a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions;</p> <p>a transmission operatively connected to said detector for transmitting control instruction to said tuner;</p> <p>a second mass medium receiver for a transmission; and</p> <p>a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 45
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising:</p> <p>a first mass medium receiver for receiving a broadcast or cablecast transmission;</p> <p>a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 45
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>receiver or said apparatus.</p>
--	------------------------------------

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 45
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

<u>least one origination transmitter before a specific time; and</u> <u>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 45
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;"><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising:</p> <p style="padding-left: 20px;">a first mass medium receiver for receiving a broadcast or cablecast transmission;</p> <p style="padding-left: 20px;">a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions;</p> <p style="padding-left: 20px;">a transmission operatively connected to said detector for transmitting control instruction to said tuner;</p> <p style="padding-left: 20px;">a second mass medium receiver for a transmission; and</p> <p style="padding-left: 20px;">a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 45
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 45
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 45
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 45
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 45
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 45
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 45
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

information including actuation or tuning control instructions;

a transmission operatively connected to said detector for transmitting control instruction to said tuner;

a second mass medium receiver for a transmission; and

a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 45
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising:</p> <ul style="list-style-type: none"> a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 45
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising:</p> <p>a first mass medium receiver for receiving a broadcast or cablecast transmission;</p> <p>a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions;</p> <p>a transmission operatively connected to said detector for transmitting control instruction to said tuner;</p> <p>a second mass medium receiver for a transmission; and</p> <p>a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 45
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>45. A system for coordinating a multimedia or multiple media presentation comprising: a first mass medium receiver for receiving a broadcast or cablecast transmission; a detector operatively connected to said first mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including actuation or tuning control instructions; a transmission operatively connected to said detector for transmitting control instruction to said tuner; a second mass medium receiver for a transmission; and a tuner operatively connected to a second mass medium receiver or to apparatus operatively connected to said second receiver for tuning said receiver or said apparatus.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

This Page Blank (uspto)

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 46
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>46. A mass medium receiver system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device;</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor;</p> <p>a decryptor for decrypting detected digital information; and</p> <p>a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 46
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>46. A mass medium receiver system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device;</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor;</p> <p>a decryptor for decrypting detected digital information; and</p> <p>a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 46
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 46
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u> <u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 46
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u> <u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 46
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal; said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>said input device.</p>
--	---------------------------

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 46
<p>116: <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

least one origination transmitter before a specific time;
and
transmitting from said at least origination
transmitter said first discrete signal and said at least
one control signal.

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 46
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>46. A mass medium receiver system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device;</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor;</p> <p>a decryptor for decrypting detected digital information; and</p> <p>a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 46
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 46
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 46
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 46
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 46
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 46
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device;</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 46
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

content;

a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor;

a decryptor for decrypting detected digital information; and

a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 46
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>46. A mass medium receiver system comprising:</p> <ul style="list-style-type: none"> a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 46
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>46. A mass medium receiver system comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device;</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor;</p> <p>a decryptor for decrypting detected digital information; and</p> <p>a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 46
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>46. A mass medium receiver system comprising: a mass medium receiver for receiving a selected broadcast or cablecast mass medium transmission and transferring programming in said transmission to a mass medium programming output device; an input device for inputting information of the reaction of a viewer to specific mass medium program content; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and transferring said detected information to a decryptor; a decryptor for decrypting detected digital information; and a controller for controlling said decryptor regarding its manner of decryption, said controller controlling said decryptor in response to information inputted by said input device.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

This Page Blank (uspto)

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 47
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 47
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 47
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 47
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u></p> <p><u>delivering said video to a transmitter;</u></p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p><u>transferring said first discrete signal to said transmitter; and</u></p> <p><u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>47. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a mass medium receiver connected to said television display;</p> <p>a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and</p> <p>a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 47
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>47. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 47
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>response to information inputted by said input device.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 47
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 47
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>47. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a mass medium receiver connected to said television display;</p> <p>a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and</p> <p>a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 47
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 47
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 47
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 47
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> <u>and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 47
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 47
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 47
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

reaction of a viewer to specific television programming;

a mass medium receiver connected to said television display;

a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and

a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 47
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>47. A multimedia or multiple media subscriber station comprising:</p> <ul style="list-style-type: none"> a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 47
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>47. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a mass medium receiver connected to said television display;</p> <p>a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and</p> <p>a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 47
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>47. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver connected to said television display; a tuner operatively connected to said mass medium receiver for causing said receiver to receive a selected transmission of programming that supplements said specific television programming; and a controller operatively connected to said input device and said tuner for controlling said tuner in response to information inputted by said input device.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 48
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller;</p> <p>a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and</p> <p>a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>

Application Claim 56

56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:

originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;

communicating one of said at least said first request and a second request to a remote data source;

receiving from said remote data source said data to serve as a basis for displaying said video presentation;

processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source and

displaying said locally generated image at said video output device in conjunction with said image from said remote video source.

Claim 56 recites methods for an environment of a receiver station, i.e., an environment that differentiates claim 56 over the patented

Application Claim 75

75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:

receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable

displaying said locally generated image at said video output device in conjunction with said image from said remote video source.

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 48
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p><u>transferring said downloadable processor instructions to a transmitter;</u></p> <p><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p><u>transferring said at least one control signal to said transmitter; and</u></p> <p><u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller;</p> <p>a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and</p> <p>a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 48
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p><u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u></p> <p><u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller;</p> <p>a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and</p> <p>a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 48
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u></p> <p><u>delivering said video to a transmitter;</u></p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller;</p> <p>a plurality of output devices, for outputting</p>

<p><u>said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>programming or information related to but distinct from said television programming; and a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>
--	--

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 48
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u> <u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</u> <u>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</u> <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p>	<p>48. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller; a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>

outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 48
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p><u>transferring said at least said first discrete signal to at least one transmitter;</u></p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p><u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller;</p> <p>a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and</p> <p>a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 48
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p><u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u></p> <p><u>transferring said at least one control signal to said at least one origination transmitter before a specific time;</u></p> <p><u>and</u></p> <p><u>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller;</p> <p>a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and</p> <p>a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 48
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television</p>

<p><u>remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p><u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u></p>	<p>programming;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller;</p> <p>a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and</p> <p>a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>
--	---

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 48
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p><u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p>

<p><u>one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller; a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>
--	--

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 48
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u></p>	<p>48. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller; a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct</p>

<u>outputting at least a portion of said video presentation based on said generated signal.</u>	from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.
---	---

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 48
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p><u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u></p> <p><u>transferring said downloadable processor instructions to a transmitter;</u></p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p><u>transferring said one or more control signals to said transmitter; and</u></p> <p><u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller;</p> <p>a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and</p> <p>a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 48
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u></p> <p><u>and</u></p> <p><u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller;</p> <p>a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and</p> <p>a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 48
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of</u></p>	<p>48. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television</p>

<u>discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of</u> <u>discrete signals at said transmitter station, wherein</u> <u>said at least said first of said plurality of discrete</u> <u>signals enables said at least one receiver station to</u> <u>process said code by organizing information</u> <u>contained in said at least said first of said plurality of</u> <u>discrete signals with information contained in a</u> <u>second of said plurality of discrete signals and,</u> <u>thereby, to respond to said code, and wherein said</u> <u>code enables said at least one receiver station to</u> <u>generate or identify a local image and output said</u> <u>local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of</u> <u>discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said</u> <u>first of said plurality of discrete signals from said</u> <u>transmitter station to said at least one receiver station.</u>	<u>programming;</u> <u>a digital detector operatively connected to a mass</u> <u>medium receiver for detecting digital information in a</u> <u>mass medium transmission and combining some of</u> <u>said detected information to a controller;</u> <u>a plurality of output devices, for outputting</u> <u>programming or information related to but distinct</u> <u>from said television programming; and</u> <u>a controller operatively connected to said input</u> <u>device, said detector and a selected output device for</u> <u>causing said output device to output specific selected</u> <u>programming or information related to but distinct</u> <u>from said television programming, said controller</u> <u>causing said output device to output said selected</u> <u>programming or information in response to</u> <u>information inputted by said input device and</u> <u>information detected by said digital detector.</u>
--	--

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 48
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a</u> <u>transmission that contains at least a first discrete signal</u> <u>of downloadable code and a first completed full-</u> <u>screen video graphic image, said first completed full-</u> <u>screen video graphic image containing at least one</u> <u>graphic image;</u> <u>passing said received first completed full-screen</u> <u>video graphic image to a video monitor for delivery to</u> <u>a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video</u> <u>graphic image at said video monitor, said displayed</u> <u>first completed full-screen video graphic image filling</u> <u>the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said</u> <u>downloadable code;</u> <u>passing said at least a first discrete signal of said</u> <u>downloadable code to at least one processor;</u> <u>organizing information contained in said at least a</u> <u>first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on at least one control signal;</u></p>	<p>48. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller; a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to</p>

<p><u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>information inputted by said input device and information detected by said digital detector.</p>
---	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 48
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u> <u>receiving at a transmitter station at least one discrete</u></p>	<p>48. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller; a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>

<p><u>signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u> <u>transferring said at least one discrete signal to a transmitter;</u> <u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 48
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of: <u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u> <u>delivering a signal to an origination transmitter, said</u></p>	<p>48. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller; a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and</p>

<p><u>signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> <u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u> <u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 48
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at</u></p>	<p>48. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of</p>

<p><u>said video monitor;</u> <u>delivering said received first completed full-screen video graphic image to a transmitter;</u> <u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> <u>transferring said one or more instruct signals to said transmitter; and</u> <u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>said detected information to a controller; a plurality of output devices, for outputting programming or information related to but distinct from said television programming; and a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>
---	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 48
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u></p>	<p>48. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a specific portion of a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining some of said detected information to a controller; a plurality of output devices, for outputting programming or information related to but distinct</p>

<p><u>passing said at least a first discrete signal to at least one processor;</u></p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p><u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>from said television programming; and</p> <p>a controller operatively connected to said input device, said detector and a selected output device for causing said output device to output specific selected programming or information related to but distinct from said television programming, said controller causing said output device to output said selected programming or information in response to information inputted by said input device and information detected by said digital detector.</p>
---	---

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 49
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>49. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer of specific television programming;</p> <p>a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and</p> <p>a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 49
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>49. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer of specific television programming;</p> <p>a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and</p> <p>a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 49
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer of specific television programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 49
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>49. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer of specific television programming;</p> <p>a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and</p> <p>a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 49
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>49. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer of specific television</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 49
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer of specific television programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>directing of said receiving means in response to information inputted by said input device.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 49
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer of specific television programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 49
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>49. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer of specific television programming;</p> <p>a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and</p> <p>a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 49
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer of specific television programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 49
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer of specific television programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 49
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer of specific television programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

<p><u>instructions to a transmitter:</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 49
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer of specific television programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 49
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer of specific television programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 49
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>display; an input device for inputting information of the reaction of a viewer of specific television programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 49
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

reaction of a viewer of specific television programming;

a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and

a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 49
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>49. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer of specific television programming;</p> <p>a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and</p> <p>a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 49
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>49. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer of specific television programming;</p> <p>a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and</p> <p>a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 49
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>49. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer of specific television programming; a means for receiving programming from a plurality of receiver, storage, computer, processor, and/or decryptor devices and operatively connected to and capable of outputting or directing said programming selectively to a plurality of storage, computer, processor, decryptor, and/or output devices; and a controller operatively connected to said receiving means for controlling the receiving, outputting, or directing of said receiving means in response to information inputted by said input device.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

This Page Blank (uspto)

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 50
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>50. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a mass medium receiver;</p> <p>a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and</p> <p>a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 50
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>50. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a mass medium receiver;</p> <p>a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and</p> <p>a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 50
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 50
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>50. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a mass medium receiver;</p> <p>a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and</p> <p>a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 50
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>50. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 50
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 50
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 50
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;"><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>50. A multimedia or multiple media subscriber station comprising:</p> <p style="padding-left: 20px;">a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p style="padding-left: 20px;">an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p style="padding-left: 20px;">a mass medium receiver;</p> <p style="padding-left: 20px;">a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and</p> <p style="padding-left: 20px;">a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 50
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 50
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 50
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	<p>inputted by said input device and information detected by said detector.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 50
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> <u>and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 50
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 50
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 50
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

reaction of a viewer to specific television programming;

a mass medium receiver;

a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and

a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 50
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>50. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a mass medium receiver;</p> <p>a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and</p> <p>a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 50
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>50. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a mass medium receiver;</p> <p>a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and</p> <p>a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 50
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>50. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a mass medium receiver; a digital detector operatively connected to said mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller; and a controller operatively connected to a tuner, a decryptor, a means for transferring, a computer, a processor or an output device for controlling said tuner, decryptor, means for transferring, computer, processor or output device in response to information inputted by said input device and information detected by said detector.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 51
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 51
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 51
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 51
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u> <u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 51
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u> <u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 51
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>received, processed, or outputted at said station or information inputted at said input device.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 51
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 51
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;"><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>51. A multimedia or multiple media subscriber station comprising:</p> <p style="padding-left: 20px;">a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p style="padding-left: 20px;">an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p style="padding-left: 20px;">a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and</p> <p style="padding-left: 20px;">a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 51
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p><u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u></p> <p><u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u></p> <p><u>passing said detected at least a first discrete signal to at least one processor;</u></p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>51. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and</p> <p>a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 51
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 51
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 51
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 51
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 51
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 51
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

reaction of a viewer to specific television programming;

a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and

a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 51
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>51. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and</p> <p>a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 51
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>51. A multimedia or multiple media subscriber station comprising:</p> <p>a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display;</p> <p>an input device for inputting information of the reaction of a viewer to specific television programming;</p> <p>a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and</p> <p>a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 51
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>51. A multimedia or multiple media subscriber station comprising: a television receiver for receiving a selected television transmission and transferring television programming in said transmission to a television display; an input device for inputting information of the reaction of a viewer to specific television programming; a digital detector operatively connected to a means for detecting digital information in a specific transmission and transferring at least some of said detected information to a storage device; and a storage device connected to said detector for receiving data on programming availability, use or usage from said detector, said storage collecting information that identifies specific programming received, processed, or outputted at said station or information inputted at said input device.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 52
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying <u>a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p> <p>receiving said transmission and displaying said program content at said television display;</p> <p>inputting reaction information of an order by a viewer for said specific programming or data;</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station;</p> <p>detecting the presence of said control instruction at said station and transferring said instruction to said controller; and</p> <p>causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 52
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each</p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for</p>

<p>of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said <u>video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p style="padding-left: 20px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p style="padding-left: 20px;">transferring said at least one control signal to said transmitter; and</p> <p style="padding-left: 20px;">transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p style="padding-left: 20px;">transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p> <p style="padding-left: 20px;">receiving said transmission and displaying said program content at said television display;</p> <p style="padding-left: 20px;">inputting reaction information of an order by a viewer for said specific programming or data;</p> <p style="padding-left: 20px;">transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station;</p> <p style="padding-left: 20px;">detecting the presence of said control instruction at said station and transferring said instruction to said controller; and</p> <p style="padding-left: 20px;">causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 52
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving, at an origination transmitter station, video</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific</p>

<p><u>to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p><u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u></p> <p><u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p> <p>receiving said transmission and displaying said program content at said television display;</p> <p>inputting reaction information of an order by a viewer for said specific programming or data;</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station;</p> <p>detecting the presence of said control instruction at said station and transferring said instruction to said controller; and</p> <p>causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 52
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein <u>at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction</u>, said method comprising the steps of:</p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission</p>

<p>receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of: transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; receiving said transmission and displaying said program content at said television display; inputting reaction information of an order by a viewer for said specific programming or data; transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station; detecting the presence of said control instruction at said station and transferring said instruction to said controller; and causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
---	---

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 52
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of: receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal</p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a</p>

<p>and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p> <p>receiving said transmission and displaying said program content at said television display;</p> <p>inputting reaction information of an order by a viewer for said specific programming or data;</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station;</p> <p>detecting the presence of said control instruction at said station and transferring said instruction to said controller; and</p> <p>causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 52
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p>

<p><u>one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; receiving said transmission and displaying said program content at said television display; inputting reaction information of an order by a viewer for said specific programming or data; transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station; detecting the presence of said control instruction at said station and transferring said instruction to said controller; and causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
---	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 52
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of: receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of <u>information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of: transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p>

<p><u>said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>receiving said transmission and displaying said program content at said television display; inputting reaction information of an order by a viewer for said specific programming or data; transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station; detecting the presence of said control instruction at said station and transferring said instruction to said controller; and causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
--	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 52
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and <u>wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device</u>, said method comprising the steps of: <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of: transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; receiving said transmission and displaying said program content at said television display; inputting reaction information of an order by a</p>

<p><u>remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p><u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u></p>	<p>viewer for said specific programming or data;</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station;</p> <p>detecting the presence of said control instruction at said station and transferring said instruction to said controller; and</p> <p>causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 52
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 40px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 40px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 40px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 40px;"><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 40px;"><u>responding to said at least one processor instruction</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p style="padding-left: 40px;">transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p>

<p><u>at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>receiving said transmission and displaying said program content at said television display; inputting reaction information of an order by a viewer for said specific programming or data; transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station; detecting the presence of said control instruction at said station and transferring said instruction to said controller; and causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
---	---

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 52
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of: transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; receiving said transmission and displaying said program content at said television display; inputting reaction information of an order by a viewer for said specific programming or data; transmitting in a mass medium transmission a</p>

	<p>control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station;</p> <p>detecting the presence of said control instruction at said station and transferring said instruction to said controller; and</p> <p>causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
--	--

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 52
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p> <p>receiving said transmission and displaying said program content at said television display;</p> <p>inputting reaction information of an order by a viewer for said specific programming or data;</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station;</p> <p>detecting the presence of said control instruction at</p>

<u>video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.	said station and transferring said instruction to said controller; and causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 52
157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of: receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</u> transmitting said one or more control signals from said origination transmitter before a specific time.	52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of: transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; receiving said transmission and displaying said program content at said television display; inputting reaction information of an order by a viewer for said specific programming or data; transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station; detecting the presence of said control instruction at said station and transferring said instruction to said controller; and causing said controller, in response to said

	instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.
--	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 52
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, <u>wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p style="padding-left: 40px;">transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; receiving said transmission and displaying said program content at said television display; inputting reaction information of an order by a viewer for said specific programming or data; transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station; detecting the presence of said control instruction at said station and transferring said instruction to said controller; and causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer,</p>

	processor, storage or output, thereby to enable said station to delivery said specific programming or data.
--	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 52
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u></p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p><u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic</p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p> <p>receiving said transmission and displaying said program content at said television display;</p> <p>inputting reaction information of an order by a viewer for said specific programming or data;</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station;</p> <p>detecting the presence of said control instruction at said station and transferring said instruction to said controller; and</p> <p>causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>

presentation.

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 52
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to <u>pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p> <p>receiving said transmission and displaying said program content at said television display;</p> <p>inputting reaction information of an order by a viewer for said specific programming or data;</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station;</p> <p>detecting the presence of said control instruction at said station and transferring said instruction to said controller; and</p> <p>causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>

<p><u>conjunction with said only a portion of said first completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 52
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p> <p>receiving said transmission and displaying said program content at said television display;</p> <p>inputting reaction information of an order by a viewer for said specific programming or data;</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station;</p> <p>detecting the presence of said control instruction at said station and transferring said instruction to said controller; and</p>

<p><u>or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u> <u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u> wherein said method delivers said video graphic presentation.</p>	<p>causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
--	---

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 52
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer;</p> <p>receiving said transmission and displaying said program content at said television display;</p> <p>inputting reaction information of an order by a viewer for said specific programming or data;</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information</p>

<p><u>graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> transferring said one or more instruct signals to said transmitter; and transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.</p>	<p>of an order exists at said station; detecting the presence of said control instruction at said station and transferring said instruction to said controller; and causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.</p>
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 52
<p>179. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed</u></p>	<p>52. A method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for a television program transmission, a television display for displaying program content associated with said transmission, an input device for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to one of a plurality of devices including a tuner, a decryptor, a transfer, a computer, a processor, a storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of: transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; receiving said transmission and displaying said program content at said television display; inputting reaction information of an order by a viewer for said specific programming or data; transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station; detecting the presence of said control instruction at</p>

<u>second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.	said station and transferring said instruction to said controller; and causing said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, transfer, computer, processor, storage or output, thereby to enable said station to delivery said specific programming or data.
---	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 53
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 53
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least</p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said</p>

<p>one control signal and programmed to process downloadable processor instructions, <u>said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of: transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 53
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said</u></p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information</p>

<p><u>video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p><u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u></p> <p><u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>
--	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 53
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises <u>information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving video at a transmitter station;</p> <p style="padding-left: 20px;">delivering said video to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at</u></p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response</p>

<p><u>least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p>transferring said first discrete signal to said transmitter; and</p> <p>transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>
---	---

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 53
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program</p>

<p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>
---	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 53
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p><u>transferring said at least said first discrete signal to at least one transmitter;</u></p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said</u></p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information</p>

<p><u>plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 53
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of: <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time;</p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of: transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a</p>

and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.
---	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 53
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device</u>, said method comprising the steps of:</p> <p>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, <u>said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of</u></p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said</p>

<p><u>receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p><u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u></p>	<p>reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>
---	---

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 53
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect</p>

	the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.
--	--

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 53
<p>143. A method of outputting a video presentation at a receiver station including:</p> <p>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p>passing said received video image to an output device for delivery to a user;</p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p><u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u></p> <p><u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u></p> <p><u>generating a signal based on said processor instructions; and</u></p> <p><u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or</p>

	output device; and delivery said specific programming or data.
--	--

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 53
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p style="padding-left: 20px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p style="padding-left: 20px;">transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p style="padding-left: 20px;">transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 53
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u></p> <p>and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 53
-----------------------	-----------------------------------

<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p style="padding-left: 20px;">transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>
---	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 53
<p>167. A method of outputting a video graphic presentation at a receiver station including: <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal</u></p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display</p>

<p><u>of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of: transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>
---	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 53
171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is	53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:

transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and

transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 53
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 53
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates

claim 177 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 53
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p><u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>53. In a method for promoting and delivering programming or data at a television subscriber station that includes a television receiver for receiving a television program transmission, a television display for displaying program content associated with said transmission, an input for inputting information of the reaction of a viewer to specific television programming, a digital detector operatively connected to a mass medium receiver for detecting digital information in a mass medium transmission and combining at least some of said detected information to a controller, the controller operatively connected to at least one of a plurality of devices including a tuner, decryptor, computer, processor, storage device or output device for controlling said devices in response to information inputted by said input device and information detected by said detector, said method comprising the steps of:</p> <p>transmitting in a television transmission program content that promotes the acquisition or purchase of specific programming or data by a viewer; and</p> <p>transmitting in a mass medium transmission a control instruction that instructs said controller to communicate a specific instruction or instructions to at least one controlled apparatus if reaction information of an order exists at said station, thereby to enable said station to receive said television transmission and display said program content at said television display; input reaction information of an order by a viewer for said specific programming or data; detect the presence of said control instruction at said station and transfer said instruction to said control; cause said controller, in response to said instruction and said reaction information of an order, to communicate a specific instruction or instructions to one of said tuner, decryptor, computer, processor, storage device or output device; and delivery said specific programming or data.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 55
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>55. A mass medium transmission receiver station comprising:</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device;</p> <p>a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and</p> <p>a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 55
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>55. A mass medium transmission receiver station comprising:</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device;</p> <p>a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and</p> <p>a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 55
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>55. A mass medium transmission receiver station comprising: an input device for inputting information of the reaction of a viewer to specific mass medium program content; a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device; a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 55
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>55. A mass medium transmission receiver station comprising:</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device;</p> <p>a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and</p> <p>a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 55
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>55. A mass medium transmission receiver station comprising:</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>said decryptor in response to information inputted by said input device; a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 55
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>55. A mass medium transmission receiver station comprising: an input device for inputting information of the reaction of a viewer to specific mass medium program content; a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device; a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>memory.</p>
--	----------------

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 55
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>55. A mass medium transmission receiver station comprising: an input device for inputting information of the reaction of a viewer to specific mass medium program content; a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device; a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 55
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>55. A mass medium transmission receiver station comprising:</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device;</p> <p>a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and</p> <p>a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 55
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p><u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u></p> <p><u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u></p> <p><u>passing said detected at least a first discrete signal to at least one processor;</u></p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>55. A mass medium transmission receiver station comprising:</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device;</p> <p>a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and</p> <p>a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 55
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>55. A mass medium transmission receiver station comprising: an input device for inputting information of the reaction of a viewer to specific mass medium program content; a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device; a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 55
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>55. A mass medium transmission receiver station comprising: an input device for inputting information of the reaction of a viewer to specific mass medium program content; a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device; a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 55
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> <u>and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>55. A mass medium transmission receiver station comprising: an input device for inputting information of the reaction of a viewer to specific mass medium program content; a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device; a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 55
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>55. A mass medium transmission receiver station comprising: an input device for inputting information of the reaction of a viewer to specific mass medium program content; a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device; a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 55
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>55. A mass medium transmission receiver station comprising: an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device;</p> <p>a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and</p> <p>a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 55
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>55. A mass medium transmission receiver station comprising:</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a first controller operatively connected to said input device for controlling a decryptor regarding its timing</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device;

a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and

a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 55
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>55. A mass medium transmission receiver station comprising:</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device;</p> <p>a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and</p> <p>a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 55
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>55. A mass medium transmission receiver station comprising:</p> <p>an input device for inputting information of the reaction of a viewer to specific mass medium program content;</p> <p>a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device;</p> <p>a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and</p> <p>a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 55
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>55. A mass medium transmission receiver station comprising: an input device for inputting information of the reaction of a viewer to specific mass medium program content; a first controller operatively connected to said input device for controlling a decryptor regarding its timing or manner of decrypting, said controller controlling said decryptor in response to information inputted by said input device; a memory device operatively connected to said first controller for holding operating instructions that control said first controller; and a second controller operatively connected to said memory device for controlling the receiving, detecting, or locating of control instructions and the inputting of said control instructions into said memory.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

This Page Blank (uspto)

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 56
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 56
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 56
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 56
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u></p> <p><u>delivering said video to a transmitter;</u></p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p><u>transferring said first discrete signal to said transmitter; and</u></p> <p><u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>56. A computer station comprising:</p> <p>a storage device for storing encrypted data;</p> <p>a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor;</p> <p>a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and</p> <p>a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 56
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>56. A computer station comprising:</p> <p>a storage device for storing encrypted data;</p> <p>a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor;</p> <p>a decryptor operatively connected to said storage device or said computer for decrypting encrypted</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 56
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 56
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 56
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>56. A computer station comprising:</p> <p>a storage device for storing encrypted data;</p> <p>a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor;</p> <p>a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and</p> <p>a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 56
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 56
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 56
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 56
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> <u>and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 56
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 56
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 56
171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u>	56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

device or said computer for decrypting encrypted data; and

a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 56
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>56. A computer station comprising:</p> <ul style="list-style-type: none"> a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 56
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>56. A computer station comprising:</p> <p>a storage device for storing encrypted data;</p> <p>a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor;</p> <p>a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and</p> <p>a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 56
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>56. A computer station comprising: a storage device for storing encrypted data; a computer operatively connected to said storage device for controlling said storage device, locating a selected portion of said data, and transferring said selected portion to a decryptor or a processor; a decryptor operatively connected to said storage device or said computer for decrypting encrypted data; and a process for locating or identifying selected information associated with said selected portion and causing said decryptor to decrypt said selected portion on the basis of said selected information.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

THE INSTANT 1987 PRIORITY SPECIFICATION

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
Column 1 lines 1-22.	<p>SIGNAL PROCESSING APPARATUS AND METHODS</p> <p>Background of the Invention</p> <p>At the present time, vast amounts of programming are transmitted through various media throughout the United States which programming is handled with significant degrees of manual processing as different, discrete units of programming transmitted on single channel systems. Broadcasters and cablecasters transmit programming with the expectation that viewers in one place tune to only one channel at a time.</p> <p>On occasion and on a limited scale, the co-ordination of two media and two channels has occurred. Such co-ordination has taken the form of stereo simulcasts where one local television station broadcasts a program, generally of classical music, and simultaneously, a local radio station broadcasts the same music in stereo. But such simulcasts require significant degrees of manual processing at both the points of origination and reception.</p> <p>Today great potential exists for a significant increase in the scope and scale of multimedia and multichannel presentations. This increase is desirable because it will increase variety and add substantially to the richness of presentations as regards both entertainment and the communications of ideas and information.</p> <p>This potential arises out of two simultaneous, independent trends. One is the development and growth of the so-called cable television industry whose member companies deliver locally not one but many channels of programming. The other is the widespread and growing ownership of computers, especially microcomputers in homes.</p> <p>It is the object of this invention to unlock this potential by the development of means and methods which permit programming to communicate with equipment that is external to television and radio receivers, particularly computers and computer peripherals such as printers.</p>	Page 7 lines 7-12.	It has no capacity for coordinating the programming content transmitted by any given peripheral system with any other programming transmitted to a television receiver. It has no capacity for controlling two separate systems such as, for example, an automatic radio and television stereo simulcast.
Column 1 lines 23-28.	<p>Today great potential exists for a significant increase in the scope and scale of multimedia and multichannel presentations. This increase is desirable because it will increase variety and add substantially to the richness of presentations as regards both entertainment and the communications of ideas and information.</p>	Page 2 lines 19-21.	Unlocking this potential is desirable because these new media will add substantial richness and variety to the communication of ideas, information and entertainment.
Column 1 lines 29-35.	<p>This potential arises out of two simultaneous, independent trends. One is the development and growth of the so-called cable television industry whose member companies deliver locally not one but many channels of programming. The other is the widespread and growing ownership of computers, especially microcomputers in homes.</p>	Page 2 lines 8-11.	Today great potential exists for combining the capacity of broadcast communications media to convey ideas with the capacity of computers to process and output user specific information.
Column 1 lines 36-41.	<p>It is the object of this invention to unlock this potential by the development of means and methods which permit programming to communicate with equipment that is external to television and radio receivers, particularly computers and computer peripherals such as printers.</p>	Page 3 lines 30-33, and page 2 line 24 to page 3 line 8.	<p>It is the object of this invention to unlock this great potential in the fullest measure by means of an integrated system of programming communication that joins together all these capacities most efficiently.</p> <p>To unlock this potential fully requires means and methods for combining and controlling receiver systems that are now separate--television and computers, radio and computers, broadcast print and computers, television and computers and broadcast print, etc. But it requires much more.</p> <p>To unlock this potential fully requires a system with efficient capacity for satisfying the demands of subscribers who have little receiver apparatus and simple information demands as well as subscribers who have extensive apparatus and complex demands. It requires capacity for transmitting and organizing vastly more information and programming than any one-channel transmission system can possibly convey at one time. It requires capacity for controlling intermediate transmission stations</p>

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
Column 1 lines 42-44	It is the further purpose of this invention to provide means and methods to process and monitor such transmissions and presentations at individual receiver sites	Page 3 lines 9-29.	that receive information and programming from many sources and for organizing the information and programming and retransmitting the information and programming so as to make the use of the information and programming at ultimate receiver stations as efficient as possible. To unlock this potential also requires efficient capacity for providing reliable audit information to (1) advertisers and others who pay for the transmission and performance of programming and (2) copyright holders, pay service operators, and others such as talent who demand, instead, to be paid. This requires capacity for identifying and recording (1) what television, radio, data, and other programming and what instruction signals are transmitted at each transmission station and (2) what is received at each receiver station as well as (3) what received programming is combined or otherwise used at each receiver station and (4) how it is received, combined, and/or otherwise used. Moreover, this system must have the capacity to ensure that programming supplied for pay or for other conditional use is used only in accordance with those conditions. For example, subscriber station apparatus must display the commercials that are transmitted in transmissions that advertisers pay for. The system must have capacity for decrypting, in many varying ways, programming and instruction signals that are encrypted and for identifying those who pirate programming and inhibiting piracy.
Column 1 lines 45-49.	and to control, in certain ways, the use of transmitted programming and the operation of certain associated equipment. Such receiver sites may be stations or systems that intend to retransmit the programming, or they may be end users of the programming.	Page 11 lines 23-27. ²	It is the further purpose of this invention to provide means and methods whereby a simplex point-to-multipoint transmission (such as a television or radio broadcast) can cause simultaneous generation of user specific information at a plurality of subscriber stations.
Column 1 lines 49-53.	The present invention contemplates that certain data may be encrypted and that certain data collected from such processing and monitoring will automatically be transferred to a remote geographic location or locations.	Page 13 lines 5-9.	In the present invention, certain monitored signals may be encrypted, and certain data collected from such monitoring may be automatically transferred from subscriber stations to one or more remote geographic stations.
Column 1 lines 54-57.	In the prior art, there have been attempts to develop systems to control programming and systems to monitor programming, but the two have been treated as separate systems, and each has had limited capacity.	Page 2 lines 24-28. ³	To unlock this potential fully requires means and methods for combining and controlling receiver systems that are now separate--television and computers, radio and computers, broadcast print and computers, television and computers and broadcast print, etc.
Column 1 line 58 to column 2 line 27.	As regards control systems, cueing systems and equipment now exist that transmit instructions to operating equipment at receiver sites by means of tone signals that are carried, in television transmissions, in the audio portion and may be heard by the human ear. Such systems and devices are used to turn on equipment such as videotape players and recorders that have been manually loaded and to tell such equipment how long to	Generally, page 4 line 17 to page 7 line 22.	This prior art is limited. It only transmits data; it does not control data processing. No system is preprogrammed to simultaneously control a plurality of central processor units, operating systems, and pluralities of computer peripheral units. None has capacity to cause simultaneous generation of user specific information at a plurality of receiver stations. None has any capacity to cause subscriber station computers to process

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490	Reference	Language	1987 Instant Specification	Language
	<p>run. Such systems operate by transmitting operating signals that precede and follow programming and are called "headers" and "trailers" respectively. The use of headers and trailers limits prior art in that headers and trailers can become separated from programming, thereby hampering automatic operations. Such prior art techniques have lacked the capacity to process the programming in various ways including to instruct receiver end equipment what specific programming to select to play or record other than that immediately at hand, how to load it on player or recorder equipment, when and how to play it or record it other than immediately, how to modify it, what equipment or channel or channels to transmit it on, when to transmit it, and how and where to file it or refile it or dispose of it. (Within television studios that are original transmitters of programming, certain systems and equipment do exist for certain automatic co-ordination of players, loaders, and other equipment; however, manual instructions still must be given, on site, for the co-ordination of such equipment which instructions are transmitted electronically on hard-wire channels that are strictly separate from the channels on which the programming is transmitted and such instructions are never broadcast.) Such prior art systems and equipment have lacked the capacity to automatically coordinate multi-channel and multi-media presentations. They have lacked the capacity to decrypt encrypted processing signals. They have lacked the capacity to monitor whether receiver-end equipment are following instructions properly.</p>		<p>received data, let alone in ways that are not inputted by the subscribers. None has any capacity to explain automatically why any given information might be of particular interest to any subscriber or why any subscriber might wish to select information that is not selected or how any subscriber might wish to change the way selected information is processed.</p> <p>...</p> <p>This prior art, too, is limited. It has no capacity to overlay any information other than information transmitted to all receiver stations simultaneously. It has no capacity to overlay any such information except in the order in which it is received. It has no capacity to cause receiver station computers to generate any information whatsoever, let alone user specific information. It has no capacity to cause overlays to commence or cease appearing at receiver stations, let alone commence and cease appearing periodically.</p> <p>As regards the automation of intermediate transmission stations, various so-called "cueing" systems in the prior art operate in conjunction with network broadcast transmissions to automate the so-called "cut-in" at local television and radio stations of locally originated programming such as so-called "local spot" advertisements.</p> <p>...</p> <p>This prior art, too, is limited. It has no capacity to schedule automatically or transmit any programming other than that loaded immediately at the play heads of the controlled video players. It has no capacity to load the video players or identify what programming is loaded on the players or verify that scheduled programs are played correctly. It has no capacity to cause the video players to record programming from any source. It has no capacity to receive programming transmissions or process received transmissions in any way. It has no capacity to operate under the control of instructions transmitted by broadcasters. It has no capacity to insert signals that convey information to or control, in any way, the automatic operation of ultimate receiver station apparatus other than television receivers.</p> <p>...</p> <p>This prior art, too, is limited. It has no capacity for interconnecting or operating a system at any time other than the time when the order to do so is entered manually at the system or remote keyboard. It has no capacity for acting on instructions transmitted by broadcasters to interconnect, actuate or tune systems peripheral to a television receiver or to actuate a television receiver or automatically change channels received by a receiver. It has no capacity for coordinating the programming content transmitted by any given peripheral system with</p>	<p>Appendix C</p> <p>Page 3 of 62</p>

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language

<p>Column 2 lines 28-63.</p>	<p>As regards monitoring systems, various systems and devices have been developed to determine what programming is played on television. One such system for monitoring programs is described in U.S. Patent to Haselwood, et al. No. 4,025,851. Another that monitors by means of audio codes that are only "substantially inaudible" is described in U.S. Patent to Crosby No. 3,845,391. Recently devices, called addressable converters, have been developed that facilitate so-called pay-per-view marketing of programming by monitoring what individual television receivers tune to and either permitting or preventing the tuners to tune to given frequencies satisfactorily. Such prior art techniques and equipment have been limited to monitoring single broadcast stations, channels or units and have lacked the ability to monitor multimedia presentations. They have been able to monitor only the audio or the video portion of television transmissions. They have been able either to monitor what is transmitted over one channel or what is received by one or more receivers but not both. They have lacked the capacity to record and transfer information simultaneously. They have been unable to decrypt encrypted signals. They have been able to monitor only single signal word types or word lengths that are placed, within the transmissions, in locations that are unvarying and unvariable. They have lacked the capacity to compare, assemble, and/or evaluate multi-word, multi-location signals. Except in the possible case of addressable converters, they have been unable to distinguish the absence of signals or signal words in transmissions. They have lacked the capacity to communicate processing instructions to external equipment as described in the paragraph above. It is the object of the present invention to overcome these and other deficiencies of the prior art.</p>	<p>Generally page 7 line 23 to page 10 line 32.</p>	<p>any other programming transmitted to a television receiver. It has no capacity for controlling two separate systems such as, for example, an automatic radio and television stereo simulcast. It has no capacity for selectively connecting radio receivers to radio peripherals such as computers or printers or speakers or for connecting computers to computer peripherals (except perhaps a television set). It has no capacity for controlling the operation of decryptors or selectively inputting transmissions to decryptors or outputting transmissions from decryptors to other apparatus. It has no capacity for monitoring and maintaining records regarding what programming is selected or played on any apparatus or what apparatus is connected or how connected apparatus operate.</p>
			<p>The prior art includes a variety of systems for monitoring programming and generating so-called "ratings." One system that monitors by means of embedded digital signals is described in U.S. Patent to Haselwood, et al. No. 4,025,851. Another that monitors by means of audio codes that are only "substantially inaudible" is described in U.S. Patent to Crosby No. 3,845,391. A third that automatically monitors a plurality of channels by switching sequentially among them and that includes capacity to monitor audio and visual quality is described in U.S. Patent to Greenberg No. 4,547,804.</p> <p>This prior art, too, is limited. It has capacity to monitor only single broadcast stations, channels or units and lacks capacity to monitor more than one channel at a time or to monitor the combining of media. At any given monitor station, it has had capacity to monitor either what is transmitted over one or more channels or what is received on one or more receivers but not both. It has assumed monitored signals of particular format in particular transmission locations and has lacked capacity to vary formats or locations or to distinguish and act on the absence of signals or to interpret and process in any fashion signals that appear in monitored locations that are not monitored signals. It has lacked capacity to identify encrypted signals then decrypt them. It has lacked capacity to record and also transfer information to a remote geographic location simultaneously.</p> <p>As regards recorder/player systems, many means and methods exist in the prior art for recording television or audio programming and/or data on magnetic, optical or other recording media and for retransmitting prerecorded programming. Video tape recorders have capacity for automatic delayed recording of television transmissions on the basis of instructions input manually by viewers. So-called "interactive video" systems have capacity for locating prerecorded television programming on a given disc and transmitting it to television receivers and locating prerecorded digital data on the same disc and transmitting them to</p>

Reference	Language	Reference	Language
			<p>computers.</p> <p>This prior art, too, is limited. It has no capacity for automatically embedding signals in and/or removing embedded signals from a television transmission then recording the transmission. It has no capacity for controlling the connection or actuation or tuning of external apparatus. It has no capacity for retransmitting prerecorded programming and controlling the decryption of said programming, let alone doing so on the basis of signals that are embedded in said programming that contain keys for the decryption of said programming. It has no capacity for operating on the basis of control signals transmitted to recorder/players at a plurality of subscriber stations, let alone operating on the basis of such signals to record user specific information at each subscriber station.</p>
Column 2 line 64 to column 3 line 12.	<p>(The term "signal unit" hereinafter means one complete signal instruction or information message unit. Examples of signal units are a unique code identifying a programming unit, or a unique purchase order number identifying the proper use of a programming unit, or a general instruction identifying whether a programming unit is to be retransmitted immediately or recorded for delayed transmission. The term "signal word" hereinafter means one full discrete appearance of a signal as embedded at one time in one location on a transmission. Examples of signal words are a string of one or more digital data bits encoded together on a single line of signal words are a string of one or more digital data bits encoded together on a single line of video or sequentially in audio. Such strings may or may not have predetermined data bits to identify the beginnings and ends of words. Signal words may contain parts of signal units, or whole signal units, or groups of partial or whole signal units or combinations.)</p>	Page 14 lines 26 to page 15 line 6.	<p>(The term "signal unit" hereinafter means one complete signal instruction or information message unit. Examples of signal units are a unique code identifying a programming unit, or a unique purchase order number identifying the proper use of a programming unit, or a general instruction identifying whether a programming unit is to be retransmitted immediately or recorded for delayed transmission. The term "signal word" hereinafter means one full discrete appearance of a signal as embedded at one time in one location on a transmission. Such strings may or may not have predetermined data bits to identify the beginnings and ends of words. Signal words may contain parts of signal units, or whole signal units, or groups of partial or whole signal units or combinations.)</p>
Column 3 lines 13-27.	<p>It is a further object of the present invention to process and monitor signals on numerous channels by sequentially scanning each channel in a predetermined manner which manner may be varied. It is also an object of the present invention to prevent unauthorized use of signals and programming by permitting signal encryption, the variation of word numbers, word lengths, word compositions, and/or word locations. It is also an object of this system to process different signal words in different ways. It is also an object of the present invention to provide a record of signals that may be transferred to a geographically distant location on command or predetermined instruction.</p> <p>Other objects of this invention will appear from the following descriptions and the appended claims.</p>	Page 3 lines 21-29. ⁴	<p>Moreover, this system must have the capacity to ensure that programming supplied for pay or for other conditional use is used only in accordance with those conditions. For example, subscriber station apparatus must display the commercials that are transmitted in transmissions that advertisers pay for. The system must have capacity for decrypting, in many varying ways, programming and instruction signals that are encrypted and for identifying those who pirate programming and inhibiting piracy.</p>
Column 3 lines 29-31.	<p>Summary of the Invention</p> <p>The present invention consists of methods and apparatus with several</p>	E.g., page 16 lines 15-27.	<p>A central objective of the present invention is to provide flexibility in regard to installed station apparatus. At any given time, the system must</p>

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
	forms.		have capacity for wide variation in individual station apparatus in order to provide individual subscribers the widest range of information options at the least cost in terms of installed equipment. Flexibility must exist for expanding the capacity of installed systems by means of transmitted software and for altering installed systems in a modular fashion by adding or removing components. Flexibility must exist for varying techniques that restrict programming to duly authorized subscribers in order to identify and deter pirates of programming.
Column 3 lines 32-37.	One method provides a technique whereby a broadcast or cablecast transmission facility can duplicate the operation of a television studio automatically through the use of instruction and information signals embedded in programming either supplied from a remote source or sources or prerecorded.	Page 11 lines 5-22,	The present invention consists of an integrated system of methods and apparatus for communicating programming. The term "programming" refers to everything that is transmitted electronically to entertain, instruct or inform, including television, radio, broadcast print, and computer programming as well as combined medium programming. The system includes capacity for automatically organizing multi-channel communications. Like television, radio, broadcast print, and other electronic media, the present invention has capacity for transmitting to standardized programming that is very simple for subscribers to play and understand. Like computer systems, the present invention has capacity for transmitting data and control instructions in the same information stream to many different apparatus at a given subscriber station, for causing computers to generate and transmit programming, and for causing receiver apparatus to operate on the basis of programming and information received at widely separated times.
Column 3 lines 37-39.	The programming may be delivered to the transmission facility by any means including broadcast, hard-wire, and manual means.	especially line 19.	It is a further purpose of this invention to provide means and methods for recording combined media and/or multi-channel programming and for playing back prerecorded programming of such types.
Column 3 lines 39-47.	The transmission facility may transmit a single channel or multiple channels of programming. The method includes a monitoring technique to construct a record for each transmitted channel that duplicates the log that the Federal Communications Commission requires broadcast station operators to maintain. The method permits the transfer of such records to a predetermined site or sites in a predetermined fashion or fashions.	Page 13 lines 10-13.	It is the further purpose of this invention to provide means and methods for the automation of intermediate transmission stations that receive and retransmit programming. The programming may be delivered by any means including over-the-air, hard-wire, and manual means. The stations may transmit programming over-the-air (hereinafter, "broadcast") or over hard-wire (hereinafter, "cablecast"). They may transmit single channels or multiple channels. The present invention includes capacity for automatically constructing records for each transmitted channel that duplicate the logs that the Federal Communications Commission requires broadcast station operators to maintain.
Column 3 line 48 to column 4 line 4.	Another method has application at receiver sites such as private homes or public places like theaters, hotels, brokerage offices, etc., whether commercial establishments or not. This method provides techniques whereby, automatically, single channel, single medium presentations,	Page 12 lines 18-29.	It is the further purpose of this invention to provide means and methods whereby a simplex point-to-multipoint transmission (such as a television or radio broadcast) can cause simultaneous generation of user specific information at a plurality of subscriber stations.
		Page 11 lines 23-27.

Reference	Language	Reference	Language
	<p>be they television, radio, or other electronic transmissions, may be recorded, co-ordinated in time with other programming previously transmitted and recorded, or processed in other fashions. Multimedia presentations may be co-ordinated in time and/or in place as, for example, when real-time video programming is co-ordinated with presentations from a microcomputer working with data supplied earlier. This method provides techniques whereby the timing and fashion of the playing, processing, and co-ordination of a presentation or presentations may be determined at the time and place of transmission or of presentation, either in whole or in part, either locally or remotely, or a combination of these factors. The method provides monitoring techniques to develop data on patterns of viewership and to permit the determination of specific usage at individual receiving sites for various purposes including, for example, the billing of individual customers. The method provides techniques whereby unauthorized use of programming and/or of signals may be prevented.</p>	<p>Page 12 line 30 to page 13 line 17.</p>	<p>It is the further purpose of this invention to provide means and methods for the automation of ultimate receiver stations, especially the automation of combined medium and multi-channel presentations. Such ultimate receiver stations may be private homes or offices or commercial establishments such as theaters, hotels, or brokerage offices.</p> <p>It is the further purpose of this invention to provide means and methods for identifying and recording what television, radio, data, and other programming is transmitted at each transmission station, what programming is received at each receiver station, and how programming is used. In the present invention, certain monitored signals may be encrypted, and certain data collected from such monitoring may be automatically transferred from subscriber stations to one or more remote geographic stations.</p> <p>It is a further purpose of this invention to provide means and methods for recording combined media and/or multi-channel programming and for playing back prerecorded programming of such types.</p> <p>It is a further purpose of this invention to provide a variety of means and methods for restricting the use of transmitted communications to only duly authorized subscribers.</p>
Column 4 lines 5-30.	<p>These techniques employ signals embedded in programs. The advantage of such embedded signals, as compared to header and trailer signals, is that they cannot become separated inadvertently from the programming and, thereby, inhibit automatic processing, that they can convey signals to equipment that must switch manners or modes of operation during transmissions of individual units of programming, and that they can be monitored. (The techniques described here may use headers and trailers from time to time.) The embedded signals may run and repeat continuously throughout the programming or they may run only occasionally or only once. They may appear in various and varying locations. In television they may appear on one line in the video portion of the transmission, or on a portion of one line, or on more than one line, and will probably lie outside the range of the television picture displayed on a normally tuned television set. In television and radio they may appear in a portion of the audio range that is not normally rendered in a form audible to the human ear. In television audio, they are likely to lie between eight and fifteen kilohertz. Signals may also be transmitted on frequencies outside the ranges of television and radio. Different and differing numbers of signals may be sent in different and differing word lengths and locations.</p>	<p>Page 13 lines 25-32.</p>	<p>The present invention employs signals embedded in programming. Embedded signals provide several advantages. They cannot become separated inadvertently from the programming and, thereby, inhibit automatic processing. They occur at precise times in programming and can synchronize the operation of receiver station apparatus to the timing of programming transmissions. They can be conveniently monitored.</p>

Reference	Language	Reference	Language
Column 4 lines 31-46.	The present invention provides a method for obscuring the meaning of the signals to prevent unauthorized use of the signals and of their associated programming. Their meanings may be obscured through encryption so that apparatus described below are necessary to decrypt them. In addition, the pattern of the composition, timing, and location of the signals may vary in such ways that only receiving apparatus that are preinformed regarding the patterns that obtain at any given time will be able to process the signals correctly. Both the arrangement of signal units in signal words and the locations, timings, and lengths of signal words in individual transmissions or groups of transmissions may vary in fashions that can only be interpreted accurately by apparatus that are preprogrammed with the keys to such variations.	Page 13 lines 14-24, Page 14 lines 16-35.	<p>It is a further purpose of this invention to provide a variety of means and methods for restricting the use of transmitted communications to only duly authorized subscribers. Such means and methods include techniques for encrypting programming and/or instructions and decrypting them at subscriber stations. They also include techniques whereby the pattern of the composition, timing, and location of embedded signals may vary in such fashions that only receiving apparatus that are preinformed regarding the patterns that obtain at any given time will be able to process the signals correctly.</p> <p>...the signals may accompany conventional print or data programming in the conventional transmission stream but will include instructions that receiver station apparatus are preprogrammed to process that instruct receiver apparatus to separate the signals from the conventional programming and process them differently. In all cases, signals may convey information in discrete words, transmitted at separate times or in separate locations, that receiver apparatus must assemble in order to receive one complete instruction.</p> <p>(The term "signal unit" hereinafter means one complete signal instruction or information message unit. Examples of signal units are a unique code identifying a programming unit, or a unique purchase order number identifying the proper use of a programming unit, or a general instruction identifying whether a programming unit is to be retransmitted immediately or recorded for delayed transmission. The term "signal word" hereinafter means one full discrete appearance of a signal as embedded at one time in one location on a transmission.</p>
Column 4 lines 47-54.	The present invention also provides a method for identifying attempts to make unauthorized use of signals and the programming associated with signals. When an apparatus finds that signal words fail to appear in places and at times when and where they are expected, the apparatus may automatically contact one or more remote sites and may or may not disable the flow of programming in one or more ways.	Page 293 line 28 to page 294 line 27.	<p>(Simultaneously other stations compare information of other selected information of bit locations that contain information of said enable-CCI3 instructions with information of other local bit locations that hold preprogrammed SPAM operating information. At each station where a match fails to occur--which suggests that the preprogrammed SPAM operating information of said station has been tampered with in an unauthorized fashion--not resulting in a match causes the controller, 20, of said station to cause all information of said local-cable-enabling-message (#7) to be erased from all memory of said station except for a particular portion of said enable-CCI3 instructions loaded at the RAM of said controller, 20, then to execute the information of said portion as information of a so-called "machine language job". Erasing said information from memory prevents the apparatus of said station from decrypting the encrypted information of said "Wall Street Week" program, and executing said portion causes said controller, 20, to cause the auto</p>

Reference	Language	Reference	Language

<p>Column 4 line 55 to column 5 line 22.</p>	<p>The present invention contemplates signal processing apparatus comprising a device or devices that can selectively scan transmission channels as directed. The channels may convey television, radio, or other transmission frequencies. The input transmissions may be received by means of antennas or from hard-wire connections. The scanners/switches, working in parallel or series or combinations, transfer the transmissions to receiver/decoder/detectors that identify signals encoded in programming transmissions and convert the encoded signals to digital information; decryptors that may convert the received information, in part or in whole, to other digital information according to preset methods or patterns; and one or more processor/monitors and/or buffer/ comparators that organize and transfer the information stream. The processors and buffers can have inputs from each of the receiver/detector lines and evaluate information continuously. From the processors and buffers, the signals may be transferred to external equipment such as computers, videotape recorders and players, etc. of decryptor/interruptor, 115. Page 294 lines 28-33.[]</p> <p>Resulting in a match causes controller, 20, to execute a particular portion of said enable-CC13 instructions.</p> <p>Executing the instructions of said portion he recorded information. The apparatus has means for external communication and an automatic dialer and can contact remote sites and transfer stored information as required in a predetermined fashion or fashions. The apparatus has a clock for determining and recording time as required. It has a read only memory for recording permanent operating instructions and other information and a programmable random access memory controller ("PRAM controller") that permits revision of operating patterns and instructions. The PRAM controller may be connected to all internal</p>	<p>Page 15 line 7 to page 16 line 10.</p>	<p>dialer, 24, and telephone connection, 22, to establish telephone communications with a particular predetermined remote station, in the fashion described above in "Operating Signal Processor Systems ... Signal Record Transfer," and causes controller, 20, then to transmit information of the aforementioned unique digital code at ROM, 21, that identifies said station and signal processor, 200, of said station uniquely as well as particular predetermined appearance-of-tampering information. Transmitting said unique code and appearance-of-tampering information enables apparatus at said remote station to identify said remote station. If telephone communications are not established with said remote station in a predetermined fashion and/or within a predetermined time interval, executing said portion causes said controller, 20, to erase all preprogrammable RAM and EPROM of the signal processing apparatus at said station, thereby disabling said apparatus.)</p> <p>In the present invention, particular signal processing apparatus (hereinafter called the "signal processor") detect signals and, in accordance with instructions in the signals and preprogramming in the signal processor, decrypt and/or record and/or control station apparatus by means of the signals and/or discard the signals. The apparatus include one or more devices that can selectively scan transmission frequencies as directed and, separately, capacity to receive signals from one or more devices that continuously monitor selected frequencies. The frequencies may convey television, radio, or other programming transmissions. The input transmissions may be received by means of antennas or from hard-wire connections. The scanners/switches, working in parallel or series or combinations, transfer the transmissions to receiver/decoder/detectors that identify signals encoded in programming transmissions and convert the encoded signals to digital information; decryptors that may convert the received information, in part or in whole, to other digital information according to preset methods or patterns; and one or more processor/monitors and/or buffer/comparators that organize and transfer the information stream. The processors and buffers can have inputs from each of the receiver/detector lines and evaluate information continuously. From the processors and buffers, the signals may be transferred to external equipment such as computers, videotape recorders and players, etc. And/or they may be transferred to one or more internal digital recorders that receive and store in memory the recorded information and have connections to one or more remote sites for further transmission of the recorded information. The apparatus has means for external communication and an automatic dialer and can contact remote sites and transfer stored information as required in a predetermined fashion or</p>

<p>The broadcast transmission is input to switch 1. Switch 1 and mixers 2 and 3 are all controlled by local oscillator and switch control 6. The oscillator, 6, is controlled to provide a number of discrete specified frequencies for the particular radio and television channels required. The switch, 1, acts to select the broadcast input or the cablecast input and passes transmissions to mixer 3 which, with the controlled oscillator, 6, acts to select a television frequency of interest that is passed at a fixed frequency to a TV signal decoder, 30.</p>	<p>inputted simultaneously to switch, 1, and mixer, 2. The broadcast transmission is inputted to switch, 1. Switch, 1, and mixers, 2 and 3, are all controlled by local oscillator and switch control, 6. The oscillator, 6, is controlled to provide a number of discrete specified frequencies for the particular radio and television channels required. The switch, 1, acts to select the broadcast input or the cablecast input and passes transmissions to mixer, 3, which, with the controlled oscillator, 6, acts to select a television frequency of interest that is passed at a fixed frequency to a TV signal decoder, 30.</p>
<p>Decoder 30 is shown more fully in Figure 2A. In the decoder, 30, the frequency passes first through filter 31 which defines the particular channel of interest to be analyzed. The television channel signal is then transmitted to a standard amplitude demodulator, 32, which uses standard demodulator techniques well known in the art to define the television base band signal. This base band signal is then transmitted through separate paths to three separate detector devices. These separate detectors are designed to act on the particular frequency ranges in which the encoded information may be found. The first path, designated A, inputs to a standard line receiver, 33, well known in the art. This line receiver, 33, detects the existence of an embedded signal or signals in one or more of the lines normally used to define a television picture.</p>	<p>Fig. 2A shows a TV signal decoder that detects signal information embedded in an inputted television frequency, renders said information into digital signals that subscriber station apparatus can process, identifies the particular apparatus to which said signals are addressed, and outputs said signals to said apparatus. Decoder, 203, in Fig. 1 is one such TV signal decoder; decoder, 30, in Fig. 2 is another.</p> <p>In Fig. 2A, a selected frequency is inputted at a fixed frequency to said decoder at filter, 31, which defines the particular channel of interest to be analyzed. The television channel signal then passes to a standard amplitude demodulator, 32, which uses standard demodulator techniques, well known in the art, to define the television base band signal. This base band signal is then transferred through separate paths to three separate detector devices. The apparatus of these separate paths are designed to act on the particular frequency ranges in which embedded signal information may be found. The first path, designated A, detects signal information embedded in the video information portion of said television channel signal. Path A inputs to a standard line receiver, 33, well known in the art. Said line receiver, 33, receives the information of one or more of the lines normally used to define a television picture. It receives the information only of that portion or portions of the overall video transmission and passes said information to a digital detector, 34, which acts to detect the digital signal information embedded in said information, using standard detection techniques well known in the art, and inputs detected signal information to controller, 39, which is considered in greater detail below. The second path, designated B, detects signal information embedded in the audio information portion of said television channel signal. Path B inputs to a standard audio demodulator, 35, which uses demodulator techniques, well known in the art, to define the television audio transmission and transfers said audio information to high pass filter, 36. Said filter, 36, defines and transfers to digital detector, 37, the portion of said audio information that is of interest. The digital detector, 37, detects signal information embedded in said audio information and inputs detected signal</p>

Reference	Language	Reference	Language

			information to controller, 39. The third path, designated C, inputs the separately defined transmission to a digital detector, 38, which detects signal information embedded in any other information portion of said television channel signal and inputs detected signal information to controller, 39. Line receiver, 33; high pass filter, 36; detectors, 34, 37, and 38; and controller, 39, all operate under control of controller, 39, and in preprogrammed fashions that may be changed by controller, 39.
Column 6 lines 57-61.	It receives and detects only that portion or portions of the overall video transmission and passes this line portion or portions to a digital detector, 34, which acts to decode the encoded signal information in the line portion or portions.	Page 354 line 16-33.	Receiving the inputted frequency of interest of wireless channel 5 at decoder, 30, causes filter, 31, to filters the inputted fixed frequency and output the one TV channel signal of channel 5 to amplitude demodulator, 32; causing demodulator, 32, to demodulate said inputted channel signal and transfer the demodulated signal to line receiver, 33; causing line receiver, 33, to detect said embedded signal information and transmit it to digital detector, 34; causing digital detector, 34, to detect the binary information of said signal information and transfer said binary information to controller, 39. Receiving said binary information at controller, 39, causes the binary SPAM information of the wireless channel 5 transmission to be checked and corrected, as necessary, at processor, 39B; converted into locally usable binary information at processor, 39D; and checked for end of file signal information at EOFs valve, 39F, and transmitted to the null output of matrix switch, 39I, until EOFs valve, 39F, detects an end of file signal. <i>See reference above.</i>
Column 6 line 61 to column 7 line 1.	The base band signal is also inputted through path B to an audio demodulator, 35, which further inputs a high pass filter, 36, and a digital detector, 37. The digital detector, 37, through standard detection techniques well known in the art, determines whether a particular signal is present in the transmission in a pre-determined fashion. Path C inputs the separately defined transmission to a digital detector, 38.	Page 34 line 21 to page 35 line 35.	
Column 7 lines 1-5.	Detectors, 34, 37, and 38, line receiver, 33, and high pass filter, 36, all operate in predetermined fashions which fashions may be changed by external controller, 20 (referring to Fig. 1), to be described below.	Page 36 line 32 to page 38 line 30.	Each decoder is controlled by a controller, 39, 44, or 47, that has buffer, microprocessor, ROM, and RAM capacities. Said buffer capacity of controller, 39, 44, or 47, includes capacity for receiving, organizing, and storing simultaneous inputs from multiple sources while inputting information, received and stored earlier, to said microprocessor capacity of controller, 39, 44, or 47. Said microprocessor capacity of controller, 39, 44, or 47, is of a conventional type, well known in the art, and is specifically designed to have particular register memories, discussed more fully below, including register capacity for detecting particular end of file signals in inputted information. The ROM capacity of controller, 39, 44, or 47, contains microprocessor control instructions of a type well known in the art and includes EPROM capacity. Said ROM and/or said EPROM may also contain one or more digital codes capable of identifying its

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification

			<p>controller, 39, 44, or 47, uniquely and/or identifying particular subscriber station functions of said controller, 39, 44, or 47. The RAM capacity of controller, 39, 44, or 47, constitutes workspace that the microprocessor of said controller, 39, 44, or 47, can use for intermediate stages of information processing and may also contain microprocessor control instructions. Capacity exists at said controller, 39, 44, or 47, for erasing said EPROM, and said RAM and said EPROM are reprogrammable.</p> <p>...</p> <p>As described above, said controller, 39, 44, or 47, controls particular apparatus of its signal decoder and has means for communicating control information to said apparatus. Said controller, 39, 44, or 47, also has means for communicating control information with a controller, 20, of a signal processor, 26. (Said communicating means is shown clearly in Fig. 2D which is discussed below.) Via said communicating means and under control of instructions and signals discussed more fully below, said controller, 20, has capacity to cause information at said EPROM to be erased and to reprogram said microprocessor control instructions at said RAM and said EPROM.</p>
Column 7 lines 6-11.	If one returns to Figure 1, one sees that the three separate lines of information outputted from TV signal decoder, 30, are then gated to a buffer/comparator, 8, which also receives other inputs from the other separate receivers comprising similar filters, demodulators, and decoders for other channels of interest.	Page 29 line 30 to page 30 line 5.	<p>At decoders, 30 and 40, signal processor, 26, identifies specific programming and its subject matter as said programming becomes available for use and/or viewing. Decoder, 30, which is shown in detail in Fig. 2A, and decoder, 40, which is shown in Fig. 2B, detect signal information embedded in the respective inputted television and radio frequencies, render said information into digital signals that subscriber station apparatus can process, modify particular ones of said signals through the addition and/or deletion of particular information, and output said signals and said modified signals to buffer/comparator, 8.</p> <p>Simultaneously, mixer, 2, and the controlled oscillator, 6, act to select a radio frequency of interest which is inputted to a radio signal decoder, 40.</p>
Column 7 lines 12-18	One such other path is that from mixer 2. Mixer 2 and the controlled oscillator, 6, act to select a radio frequency of interest which is inputted to a radio signal decoder, 40, shown in Figure 2B. The frequency passes first through standard radio receiver circuitry, 41, well known in the art, a radio decoder, 42, and a standard digital detector, 43.	Page 29 lines 26-29. ⁷	
Column 7 lines 18-21.	All operate in predetermined fashions that may be changed by external controller, 20 (referring to Fig. 1). As Figure 1 shows, the radio signal detector outputs to buffer/comparator 8.	Page 36 line 32 to page 38 line 30.	<i>See reference above.</i>
Column 7 lines 22-34.	(The signal processor apparatus described here is configured to receive broadcast TV transmissions and cablecast TV and radio transmissions. Were it desirable to process signals in other transmissions such as broadcast microwave transmissions or cablecast transmissions on other than standard TV and radio frequencies, the mixers and switches would	Page 33 lines 25-33. ⁸	As an apparatus in the unified system of programming communication of the present invention, a signal processor can monitor any combination of inputs and transmission frequencies, and the signal processor of Fig. 2 is but one embodiment of a signal processor. Other embodiments can receive and monitor available programming in transmission frequencies

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language

	be appropriately reconfigured and one or more other signal decoders as described in Figure 2C would be added. As Figure 2C shows, the desired frequencies would pass through appropriate other receiver circuitry, 45, well known in the art, and an appropriate digital detector, 46, before being outputted to buffer/comparator 8.		other than radio and television frequencies through the addition of one or more other signal decoders such as that of Fig. 2C described below.
Column 7 lines 34-35.	These, too, can be controlled by controller, 20 (ref. to Fig. 1.)	Page 36 line 32 to page 38 line 30.	<i>See reference above.</i>
Column 7 lines 36-43.	Buffer/comparator, 8, organizes the data stream that it receives according to a pre-determined fashion that enables buffer/comparator, 8, among other things, to assemble signal units from signal words. In a pre-determined fashion, buffer/comparator, 8, identifies signal words and/or signal units that must be decrypted, either in whole or in part, and passes identified signal words and/or units to decryptor, 10.	Page 30 lines 7-30.	Buffer/comparator, 8, receives said signals from said decoders and other signals from other inputs and organizes the received information in a predetermined fashion. Buffer/comparator, 8, has capacity for comparing a particular portions or portions of inputted information to particular preprogrammed information and for operating in preprogrammed fashions on the basis of the results of said comparing. It has capacity for detecting particular end of file signals in inputted information and for operating in preprogrammed fashions whenever said information is detected. The process of communication metering commences at buffer/comparator, 8. In a predetermined fashion, buffer/comparator, 8, determines whether a given instance of received signal information requires decryption, either in whole or in part. In a fashion described more fully below, buffer/comparator, 8, and a controller, 20, which, too, is described more fully below, determine whether signal processor, 26, is enabled to decrypt said information. If signal processor, 26, is so enabled, buffer/comparator, 8, transfers said information to decryptor, 10. If signal processor, 26, is not so enabled, buffer/comparator, 8, discards said information in a predetermined fashion. Buffer/comparator, 8, transfers signals that do not require decryption directly to processor or controller, 12.
Column 7 lines 43-49.	Decryptor, 10, uses conventional decrypter techniques, well known in the art, in a pre-determined fashion to decrypt such signals as required. Decryptor, 10, then passes the decrypted signals to processor or monitor, 12. Buffer/comparator, 8, passes signal words and units not identified as requiring decryption directly to processor or monitor, 12.	Page 30 line 21 to page 31 line 2.	In a fashion described more fully below, buffer/comparator, 8, and a controller, 20, which, too, is described more fully below, determine whether signal processor, 26, is enabled to decrypt said information. If signal processor, 26, is so enabled, buffer/comparator, 8, transfers said information to decryptor, 10. If signal processor, 26, is not so enabled, buffer/comparator, 8, discards said information in a predetermined fashion. Buffer/comparator, 8, transfers signals that do not require decryption directly to processor or controller, 12. Decryptor, 10, is a standard digital information decryptor, well known in the art, that receives signals from buffer/comparator, 8, and under control of said controller, 20, uses conventional decrypter techniques, well known in the art, to decrypt said signals as required. Decryptor, 10, transfers decrypted signals to controller, 12.

Reference	Language	Reference	Language
Column 7 lines 50-64.	Processor or monitor, 12, analyzes, in a pre-determined fashion, the signal words and units that it receives and determines whether they are to be passed to external equipment or to buffer/comparator, 14, for further processing or both. If a signal or signals are to be passed externally, processor unit, 12, identifies, in a pre-determined fashion, the external equipment to which the signal or signals are addressed and passes them to appropriate jack ports for external transmission. If they are to be processed further, processor or monitor, 12, passes them to buffer/comparator, 14. Processor or monitor, 12, communicates with clock, 18, and has means to delay the transfer of signals, in a predetermined fashion, when delayed transfer is determined, in a predetermined fashion, to be required.	Page 31 lines 2-29.	<p>Controller, 12, is a standard controller, ...</p> <p>Controller, 12, is a standard controller, well known in the art, that has microprocessor and RAM capacities and one or more ports for transmitting information to external apparatus. Said microprocessor capacity of controller, 12, is of a conventional type, well known in the art, but is specifically designed to have particular register memories, discussed more fully below. Controller, 12, may contain read only memory (hereinafter, "ROM").</p> <p>Controller, 12, receives the signals inputted from buffer/comparator, 8, and decryptor, 10; analyzes said signals in a predetermined fashion; and determines whether they are to be transferred to external equipment or to buffer/comparator, 14, or both. If a signal or signals are to be transferred externally, in a predetermined fashion controller, 12, identifies the external apparatus to which the signal or signals are addressed and transfers them to the appropriate port or ports for external transmission. If they contain meter and/or monitor information and are to be processed further, controller, 12, selects, assembles, and transfers the appropriate information to buffer/comparator, 14. Controller, 12, has capacity to modify received signals by adding and/or deleting information and can transfer a given signal to one apparatus with one modification and to another apparatus with another modification (or with no modification). Controller, 12, receives time information from clock, 18, and has means to delay in a predetermined fashion the transfer of signals when, in a predetermined fashion, delayed transfer is determined to be required.</p>
Column 7 line 65 to column 8 line 12.	Buffer/comparator, 14, has means for identifying, according to a predetermined fashion, which signals are to be recorded. To avoid overloading digital recorder, 16, with duplicate data, buffer/comparator, 14, has means for counting and discarding duplicate signals. Buffer/comparator, 14, is connected to clock, 18, and has means for adding information such as time of receipt, for example, to signals. Upon determining in a pre-determined fashion that a signal word or unit should be passed, buffer/comparator, 14, transmits the combined information to a digital recorder, 16. Buffer/ comparator, 14, also has means for determining, in a pre-determined fashion, when signals require transfer immediately to a remote site and for communicating such a requirement to controller, 20, and such signals directly with the remote site via telephone connection, 22.	Page 31 line 30 to page 32 line 33.	<p>Buffer/comparator, 14, receives signal information that is meter information and/or monitor information from controller, 12, and from other inputs; organizes said received information into meter records and/or monitor records (called, in aggregate, hereinafter, "signal records") in a predetermined fashion or fashions; and transmits said signal records to a digital recorder, 16, and/or to one or more remote sites. With respect to particular simple or frequently repeated instances of signal information, buffer/comparator, 8, has capacity to determine, in a predetermined fashion or fashions, what received information should be recorded, how it should be recorded, and when it should be transmitted to recorder, 16, and/or to said remote sites and to initiate or modify signal records and to discard unnecessary information accordingly. To avoid overloading digital recorder, 16, with duplicate data, buffer/comparator, 14, has means for counting and/or discarding duplicate instances of particular signal information and for incorporating count information into signal records. Buffer/comparator, 14, receives time information from clock, 18, and has means for incorporating time information into signal records.</p>

			Buffer/comparator, 14, also has means for transferring received information immediately to a remote site or sites via telephone connection, 22, and for communicating a requirement for such transfer to controller, 20, which causes such transfer. Buffer/comparator, 14, operates under control of controller, 20, and has capacity whereby controller, 20, can cause modification of the formats of and information in signal records at buffer/comparator, 14. (In circumstances where information collecting and processing functions are extensive—for example, when a given buffer/comparator, 14, must collect monitor information at a subscriber station with apparatus and/or communications flows that are extensive and complex—buffer/comparator, 14, may operate under control of a dedicated, so-called "on-board" controller, 14A, at buffer/comparator, 14, which is preprogrammed with appropriate control instructions and is controlled by controller, 20, similarly to the fashion in which controller, 12 is controlled by controller, 20.)	
Column 8 line 13-19.	Digital recorder, 16, may be a memory storage element of standard design. It has means for determining in a pre-determined fashion how full it is and passing this information to controller, 20. The pre-determined fashion may include provisions whereby recorder, 16, informs controller, 20, automatically when it reaches a certain level of fullness.	Page 32 line 34 to page 33 line 6.	Digital recorder, 16, is a memory storage element of standard design that receives information from buffer/comparator, 14, and records said information in a predetermined fashion. In a predetermined fashion, recorder, 16, can determine how full it is and transmit this information to controller, 20. Recorder, 16, may inform controller, 20, automatically when it reaches a certain level of fullness.	
Column 8 lines 20-27.	The signal processor apparatus also has a controller device which includes programmable random access memory controller 20, read only memory 21 that may contain a unique digital code capable of identifying the signal processing apparatus uniquely, an automatic dialing device 24, and a telephone unit, 22. The controller, 20, governs the operation of all operating elements of the apparatus.	Page 33 lines 7-26. ¹⁰	Signal processor, 26, has a controller device which includes programmable RAM controller, 20; ROM, 21, that may contain unique digital code information capable of identifying signal processor, 26, and the subscriber station of said processor, 26, uniquely; an automatic dialing device 24; and a telephone unit, 22. A particular portion of ROM, 21, is erasable programmable ROM (hereinafter, "EPROM") or other forms of programmable nonvolatile memory. Under control particular preprogrammed instructions at that portion of ROM, 21, that is not erasable, signal processor, 26, has capacity to erase and reprogram said EPROM in a fashion that is described more fully below. Controller, 20, has capacity for controlling the operation of all elements of the signal processor and can receive operating information from said elements. Controller, 20, has capacity to turn off any element or elements of controlled subscriber station apparatus, in whole or in part, and erase any or all parts of erasable memory of said controlled apparatus. As an apparatus in the unified system of programming communication of the present invention, a signal processor...	
Column 8 lines 27-32.	The controller, 20, inputs the local oscillator, 6, a sequential pattern to select the various channels to be received by switch, 1, and mixers, 2 and 3. This then allows the channels to be diverted to the detectors,	Page 29 lines 17-29. ¹¹	Switch, 1, and mixers, 2 and 3, are all controlled by local oscillator and switch control, 6. The oscillator, 6, is controlled to provide a number of discrete specified frequencies for the particular radio and television

Reference	Language	Reference	Language
	receivers, and decoders in any predetermined pattern desired.		channels required. The switch, 1, acts to select the broadcast input or the cablecast input and passes transmissions to mixer, 3, which, with the controlled oscillator, 6, acts to select a television frequency of interest that is passed at a fixed frequency to a TV signal decoder, 30. Simultaneously, mixer, 2, and the controlled oscillator, 6, act to select a radio frequency of interest which is inputted to a radio signal decoder, 40.
Column 8 lines 32-39.	The controller, 20, can instruct signal decoders, 30 and 40, when, where, and how to look for signal words, which allows signal words to be received in any pattern or patterns. It can instruct buffer/comparator, 8, how to assemble signal words into signal units and join units together for further transfer and how to determine which signals to pass to decrypter, 10.	Page 38 lines 19-30. ¹²	As described above, said controller, 39, 44, or 47, controls particular apparatus of its signal decoder and has means for communicating control information to said apparatus. Said controller, 39, 44, or 47, also has means for communicating control information with a controller, 20, of a signal processor, 26. (Said communicating means is shown clearly in Fig. 2D which is discussed below.) Via said communicating means and under control of instructions and signals discussed more fully below, said controller, 20, has capacity to cause information at said EPROM to be erased and to reprogram said microprocessor control instructions at said RAM and said EPROM.
Column 8 lines 39-44.	It can tell decrypter, 10, when and how to change decryption patterns, fashions, and techniques. It can tell processor or monitor, 12, how to	Page 30 lines 31-35. ¹³	Decryptor, 10, is a standard digital information decryptor, well known in the art, that receives signals from buffer/comparator, 8, and under control of said controller, 20, uses conventional decryptor techniques, well known in the art, to decrypt said signals as required.
Column 8 lines 45-47.	determine which signals to pass externally and when and where and how to determine which signals to pass to buffer/comparator, 14. It can tell buffer/comparator, 14, what and how to count, what and how to mark signals, and what received signals to discard. The controller, 20, also inputs the digital recorder, 16,	Page 32 lines 20-33. ¹⁴	Buffer/comparator, 14, operates under control of controller, 20, and has capacity whereby controller, 20, can cause modification of the formats of and information in signal records at buffer/comparator, 14. (In circumstances where information collecting and processing functions are extensive—for example, when a given buffer/comparator, 14, must collect monitor information at a subscriber station with apparatus and/or communications flows that are extensive and complex—buffer/comparator, 14, may operate under control of a dedicated, so-called "on-board" controller, 14A, at buffer/comparator, 14, which is preprogrammed with appropriate control instructions and is controlled by controller, 20, similarly to the fashion in which controller, 12 is controlled by controller, 20.)
Column 8 lines 47-50.	to direct it to output the information from the memory of the recorder, 16, to telephone connection, 22, and thence to the collection site at the remote geographical location.	Page 271 lines 32 to page 278 line 20.	OPERATING SIGNAL PROCESSOR SYSTEMS ... SIGNAL RECORD TRANSFER In examples #3, #4, and #5, the transmission of SPAM signal information causes signal processor, 200, to transfer signal record information by telephone to remote station computers. At the outset of each example, recorder, 16, has reached a level of fullness where recording the next signal record will cause the quantity of recorded information to equal or exceed the particular fullness information of said recorder, 16. In

Reference	Language	Reference	Language
62-65.	for controller, 20, and pass them to controller, 20, over control information lines.	17-22.	30, PRAM controller, 20, and switch controller, 20A, that exist within the equipment case of a signal processor, 200, are inputted to said apparatus from controller, 12, via controller, 20, rather than via matrix switch, 259.)
Column 8 lines 65-68	Buffer/comparator, 14, has the capacity to pass received time signals to the controller, 20, in a predetermined fashion set by and changeable by controller, 20.	Page 179 lines 22-35. ¹⁷	Not resulting in a match causes onboard controller, 14A, to cause signal processor, 200, to record said record of prior programming at recorder, 16. Automatically, under control of said process-monitor-info instructions, onboard controller, transmits to controller, 20, a particular preprogrammed instruct-to-record instruction that causes controller, 20, to cause onboard controller, 14A, to transmit the monitor record of said prior programming to recorder, 16, in a predetermined fashion and that causes controller, 20, to cause recorder, 16, to record said monitor record information in a predetermined fashion. (Certain transfer functions caused by said transmission of instruct-to-record information are described more fully below in "Operating Signal Processing Systems ... Signal Record Transfer.")
Column 8 line 68 to column 9 line 4.	Buffer/comparator, 8, and monitor or processor, 12, each have the capacity to inform controller, 20, when signals that they are instructed to look for in predetermined fashions, set by and changeable by controller, 20, fail to appear.	Page 301 lines 6-11. ¹⁸	At each station where a match fails to occur—which indicates that a decryptor, 224, is not decrypting its received information correctly and suggests that the preprogrammed SPAM operating information of said station may have been tampered with—not resulting in a match causes the controller, 20,....
Column 9 lines 4-8.	Oscillator, 6, the controller, 20, and buffer/comparator, 8, can interact in such a fashion that buffer, 8, can identify the channel that any given signal is received on and mark the signal for subsequent identification of the channel.	Page 249 lines 6-33. ¹⁹	In example #5, the "Wall Street Week" combining synch commands are transmitted unencrypted as in the first example, and the "Wall Street Week" program is transmitted on the frequency of channel 13 by a wireless broadcast station whose transmission is retransmitted on the frequency of channel 13 on said cable. Thus a viewer can tune to the "Wall Street Week" program on either wireless channel 13 or cable channel 13. Simultaneously, different programs are transmitted on each of the other television and radio transmissions. Controller, 20, has preprogrammed the RAM associated with the control processor, 39J, of the controller, 39, of decoder, 30, with bit information of a channel mark associated with each transmission of television programming received at decoder, 30. (While wireless channel 13 and cable channel 13 may transmit the same programming, they have different channel marks.) At said RAM, said control processor, 39J, maintains, associated with appropriate channel mark information, monitor information records of the last command containing meter-monitor program identification information inputted via each channel transmission. Said records include program unit identification information. At the outset of the example, no transmission of "Wall Street Week" program unit identification information has yet occurred, and the program unit information associated with the source mark of wireless channel 13 and,

Column 9 lines 8-19.	Digital recorder, 16, can tell the controller, 20, when it reaches predetermined levels of fullness to permit the controller, 20, to instruct auto dialer, 24, to contact an appropriate remote site allowing the recorder, 16, to output its data making memory available. In normal operation, controller, 20, may be instructed by the remote site to erase recorder, 16, which instruction controller, 20, effects through communication with recorder, 16; however, controller may ignore such an instruction in a predetermined fashion, if the information in recorder, 16, is to be conveyed to more than one remote sites.	Page 33 lines 4-6. ²⁰	separately, with the source mark of cable channel 13 is the unit information of the television programming transmitted immediately before the start of the "Wall Street Week" transmission. Signal processor, 26, has a controller device which includes programmable RAM controller, 20; ROM, 21, that may contain unique digital code information capable of identifying signal processor, 26, and the subscriber station of said processor, 26, uniquely; an automatic dialing device 24; and a telephone unit, 22. A particular portion of ROM, 21, is erasable programmable ROM (hereinafter, "EPROM") or other forms of programmable nonvolatile memory. Under control particular preprogrammed instructions at that portion of ROM, 21, that is not erasable, signal processor, 26, has capacity to erase and reprogram said EPROM in a fashion that is described more fully below. Controller, 20, has capacity for controlling the operation of all elements of the signal processor and can receive operating information from said elements. Controller, 20, has capacity to turn off any element or elements of controlled subscriber station apparatus, in whole or in part, and erase any or all parts of erasable memory of said controlled apparatus.
Column 9 lines 20-25.	The controller, 20, can shut off any element or elements of the apparatus in whole or in part. It is interactive with external sources via telephone connection, 22, and can be reprogrammed from such remote sources. It follows standard password protection techniques well known in the art.	Page 33 lines 7-24. ²¹	Signal processor, 26, has a controller device which includes programmable RAM controller, 20; ROM, 21, that may contain unique digital code information capable of identifying signal processor, 26, and the subscriber station of said processor, 26, uniquely; an automatic dialing device 24; and a telephone unit, 22. A particular portion of ROM, 21, is erasable programmable ROM (hereinafter, "EPROM") or other forms of programmable nonvolatile memory. Under control particular preprogrammed instructions at that portion of ROM, 21, that is not erasable, signal processor, 26, has capacity to erase and reprogram said EPROM in a fashion that is described more fully below. Controller, 20, has capacity for controlling the operation of all elements of the signal processor and can receive operating information from said elements. Controller, 20, has capacity to turn off any element or elements of controlled subscriber station apparatus, in whole or in part, and erase any or all parts of erasable memory of said controlled apparatus.
Column 9 lines 26-31.	Operation of Signal Processor Apparatus The simplest forms of signal processor apparatus are each of the five paths described in Figures 2A, 2B, and 2C. Each path, by itself, is capable of identifying signals in the portions of programming transmissions that each receives.	Page 34 line 18 to page 38 line 30.	Signal decoder apparatus such as decoder, 203, in Fig. 1 and decoders, 30 and 40, in Fig. 2 are basic in the unified system of this invention. Fig. 2A shows a TV signal decoder that detects signal information embedded in an inputted television frequency, renders said information into digital signals that subscriber station apparatus can process, identifies the particular apparatus to which said signals are addressed, and outputs said signals to said apparatus. Decoder, 203, in Fig. 1 is one such TV signal decoder; decoder, 30, in Fig. 2 is another.

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
Column 9 lines 31-40.	A digital signal is embedded by conventional generating and encoding means and transmitted in a television, radio or other transmission. Each path is capable of receiving a transmission or a portion of a transmission and detecting digital signals in that portion and transmitting said signals to in-line equipment for further processing. Each of the paths described in Figures 2A, 2B, and 2C can identify and process only signals embedded in the particular transmission channel	Page 22 lines 1-6.	<p>In Fig. 2A, a selected frequency is inputted at a fixed frequency to said decoder at filter, 31, which defines the particular channel of interest to be analyzed. The television channel signal then passes to a standard amplitude demodulator, 32, which uses standard demodulator techniques, well known in the art, to define the television base band signal. This base band signal is then transferred through separate paths to three separate detector devices. The apparatus of these separate paths are designed to act on the particular frequency ranges in which embedded signal information may be found. The first path, designated A, detects signal information embedded in the video information portion of said television channel signal. Path A inputs to a standard line receiver, 33, well known in the art. Said line receiver, 33, receives the information of one or more of the lines normally used to define a television picture. It receives the information only of that portion or portions of the overall video transmission and passes said information to a digital detector, 34, which acts to detect the digital signal information embedded in said information, using standard detection techniques well known in the art, and inputs detected signal information to controller, 39, which is considered in greater detail below. The second path, designated B, detects signal information embedded in the audio information portion of said television channel signal. Path B inputs to a standard audio demodulator, 35, which uses demodulator techniques, well known in the art, to define the television audio transmission and transfers said audio information to high pass filter, 36. Said filter, 36, defines and transfers to digital detector, 37, the portion of said audio information that is of interest. The digital detector, 37, detects signal information embedded in said audio information and inputs detected signal information to controller, 39. The third path, designated C, inputs the separately defined transmission to a digital detector, 38, which detects signal information embedded in any other information portion of said television channel signal and inputs detected signal information to controller, 39. Line receiver, 33; high pass filter, 36; detectors, 34, 37, and 38; and controller, 39, all operate under control of controller, 39, and in preprogrammed fashions that may be changed by controller, 39.</p> <p>... a first series of control instructions is generated, embedded sequentially on said line or lines of the vertical interval, and transmitted on the first and each successive frame of said television program transmission, signal unit by signal unit and word by word, until said series has been transmitted in full.</p>

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
Column 9 lines 41-47.	inputted to said paths. The signal processor apparatus described in Figure 1 can identify such signals in multiple and variable locations in multiple and variable modes, channels, and transmissions. Such signals may be transmitted over and over continuously in such transmissions or they may be transmitted over and over only for predetermined time intervals.	Page 248 line 13 to page 271 line 30. ²³	<i>Length of passage precludes inclusion here.</i>
Column 9 lines 47-52.	The controller, 20, is programmed to sequence the local oscillator, 6, to select each desired frequency for a specific time interval in accordance with a predetermined pattern. This pattern may be selected in accordance with standard broadcast and cablecast practices known to exist on that transmission line or frequency.	Page 248 line 17 to page 249 line 5.	Signal processor, 200, is preprogrammed with information that identifies each cable and over-the-air (hereinafter, "wireless") transmission or frequency in the locality of the subscriber station of Fig. 3 as well as the standard broadcast and cablecast practices that apply on said transmissions and frequencies. Via a conventional multi-channel cable transmission, in a fashion well known in the art, four channels of conventional television programming and two conventional FM radio signals are inputted to a first alternate contact of switch, 1, and to mixer, 2. Said television channels are transmitted normally assigned to channels 2, 4, 7, and 13 of the television frequency spectrum. Said radio signals are transmitted on 99.0 MHz and 100.0 MHz of the FM frequency spectrum. Via a conventional television receiving antenna, three conventional wireless television transmissions are inputted to the second alternate contact of switch, 1. Said wireless transmissions are on the frequencies of the television spectrum normally assigned to channels 5, 9, and 13. In a predetermined fashion, controller, 20, controls oscillator, 6, to sequence local oscillator, 6, in the pattern: cable channel 2, cable channel 4, cable channel 7, cable channel 13, wireless channel 5, wireless channel 9, wireless channel 13, then to repeat said pattern.
Column 9 lines 53-63.	The local oscillator, being thus sequenced, will allow each signal decoder, 30 and 40, to receive a particular frequency at a particular time interval. This will define the timing of the composite outputs of the digital detectors, 34, 37, and 38 in Figure 2A, and 43 in Figure 2B. The same controller will control buffer/comparator, 8, to discard received duplicate and partial signals, to mark signals with correct channel identifiers, to transfer signals to decrypter, 10, and processor or monitor, 12, as required, and to perform such other functions as buffer/comparator, 8, performs.	Page 248 line 13 to page 271 line 30. ²⁴	<i>Length of passage precludes inclusion here.</i>
Column 9 lines 63-65.	The controller, 20, instructs decrypter, 10, what to decrypt and in what fashion.	Page 147 line 19 to page 150 line 6.	Because the subscriber station of Fig. 3 is preprogrammed with all information needed to decrypt said second message, the aforementioned match with said decrypt-with-key-J information causes controller, 20, to execute particular preprogrammed decrypt-with-J instructions. Among said preprogrammed instructions is key information of J, and said instructions cause controller, 20, automatically to select and transfer said

Column 10 lines 14-23.	Method of Use at an Intermediate Transmission Point The signal processing apparatus outlined in Figures 1, A, 2B, and 2C, and their variants as appropriate, can be used to automate the operations of an intermediate transmission point whether it be a broadcast station transmitting only a single channel of programming or a cable system cablecasting many channels. They can be used in a facility transmitting television programming, radio programming, and making other electronic transmissions.	Page 324 lines 7-17.	information to telephone connection, 22, which causes said connection, 22, to transmit said records and information to said first computer. AUTOMATING INTERMEDIATE TRANSMISSION STATIONS The signal processing apparatus outlined in Figs. 2, 2A, 2B, 2C, and 2D, and their variants as appropriate, can be used to automate the operations of intermediate transmission stations that receive and retransmit programming. The stations so automated may transmit any form of electronically transmitted programming, including television, radio, print, data, and combined medium programming and may range in scale of operation from wireless broadcast stations that transmit a single programming transmission to cable systems that cablecast many channels simultaneously.
Column 10 lines 24-52.	FIGS. 3A, 3B and 3C illustrates one instance of such use. Figure 3 illustrates the use of Signal Processing Apparatus and Methods at a cable television system "head end" transmission facility that cablecasts several channels of television programming. The means for and method of transmission of programming described here is well known in the art. The facility receives programming from many sources. Transmissions may be received from satellites by satellite antenna, 50, low noise amplifiers, 51 and 52, and TV receivers, 53, 54, 55, and 56. Microwave transmissions can be received by microwave antenna, 57, and television video and audio receivers, 58 and 59. Conventional TV broadcast transmissions can be received by antenna, 60, and TV demodulator, 61. Other electronic programming transmissions are received by other programming input means, 62. Each receiver/modulator/input apparatus, 53 through 62, transfers its received transmissions into the station by hard-wire to a conventional matrix switch, 75, well known in the art, that outputs to one or more recorder/players, 76 and 78, and/or to apparatus that outputs said transmissions over various channels to the cable system's field distribution system, 93, which apparatus includes cable channel modulators, 83, 87, and 91, and channel combining and multiplexing system, 92. Programming can also be manually delivered to said station on prerecorded videotapes and videodiscs. When played on video recorders, 76 and 78, or other similar equipment well known in the art, such as prerecorded programming can be transmitted via switch 75 to field distribution system, 93.	Page 324 line 18 to page 325 line 9.	Fig. 6 illustrates Signal Processing Apparatus and Methods at an intermediate transmission station that is a cable television system "head end" and that cablecasts several channels of television programming. The means and methods for transmitting conventional programming are well known in the art. The station receives programming from many sources. Transmissions are received from a satellite by satellite antenna, 50, low noise amplifiers, 51 and 52, and TV receivers, 53, 54, 55, and 56. Microwave transmissions are received by microwave antenna, 57, and television video and audio receivers, 58 and 59. Conventional TV broadcast transmissions are received by antenna, 60, and TV demodulator, 61. Other electronic programming transmissions are received by other programming input means, 62. Each receiver/modulator/input apparatus, 53 through 62, transfers its received transmissions into the station by hard-wire to a conventional matrix switch, 75, well known in the art, that outputs to one or more recorder/players, 76 and 78, and/or to apparatus that outputs said transmissions over various channels to the cable system's field distribution system, 93, which apparatus includes cable channel modulators, 83, 87, and 91, and channel combining and multiplexing system, 92. Programming can also be manually delivered to said station on prerecorded videotapes and videodiscs. When played on video recorders, 76 and 78, or other similar equipment well known in the art, such as prerecorded programming can be transmitted via switch 75 to field distribution system, 93.
Column 10 lines 53-57.	In the present art, the identification of incoming programming, however received; the operation of video player and recorder equipment, 76 and 78; and the maintenance of records of programming transmissions are all largely manual operations.	Page 325 lines 10-14.	In the prior art, the identification of incoming programming, however received; the operation of video player and recorder equipment, 76 and 78; and the maintenance of records of programming transmissions are all largely manual operations.

58-60. Column 10 line 61 to column 11 line 1.	apparatus and methods to automate these and other operations. Incoming programing transmissions are received at the relevant receiver points, antennas, 50, 57, and 60, and other means, 62. They are fed along the conventional paths described above. At distribution amplifiers, 63 through 70, each incoming feed is split into two paths. One is the conventional path whereby programing has flowed and continues to flow to recording devices, 76 and 78, and/or to flow to field distribution system, 93.	15-16. Page 325 lines 17-33.	methods to automate these and other operations. In line between each of the aforementioned receiver/ demodulator/input apparatus, 53, 54, 55, 56, 57, 58, 59, 60, 61, or 62, and matrix switch, 75, is a dedicated distribution amplifier, 63, 64, 65, 66, 67, 68, 69, or 70, that splits each incoming feed into two paths. One path is the conventional path whereby programming flows from each given receiver/demodulator/input apparatus, 53, 54, 55, 56, 57, 58, 59, 60, 61, or 62, to matrix switch, 75. The other path inputs the transmission of said given receiver/demodulator/ input apparatus, 53, 54, 55, 56, 57, 58, 59, 60, 61, or 62, individually to signal processor system, 71. (In other words, distribution amplifier, 63, continuously inputs the programming transmission of receiver, 53, to matrix switch, 75, and separately to signal processor system, 71; distribution amplifier, 64, inputs the programming transmission of receiver, 54, to matrix switch, 75, and separately to signal processor system, 71; etc.)
Column 11 lines 1-11.	The other path flows from each distribution amplifier, 63 through 70, individually to signal processor, 71. Signal processor, 71, has means, described above, to identify and separate the instruction and information signals from their associated programing and pass them, along with information identifying the channel source of each signal, externally to code reader, 72. Signal processor, 71, also has means to record said signals and transfer them to external communications network, 97. It also has means to record and transfer simultaneously.	Page 325 line 34 to page 326 line 15.	At signal processor system, 71, which is a system as shown in Fig. 2D, the outputted transmission of each distribution amplifier, 63, 64, 65, 66, 67, 68, 69, or 70, is inputted into a dedicated decoder (such as decoders, 27, 28, and 29 in Fig. 2D) that processes continuously the inputted transmission of said distribution amplifier, 63, 64, 65, 66, 67, 68, 69, or 70; selects SPAM messages in said transmission that are addresses to ITS apparatus of said intermediate transmission station; automatically adds, in a predetermined fashion, source mark information that identifies said associated distribution amplifier, 63, 64, 65, 66, 67, 68, 69, or 70; and transfers said selected messages, with said source mark information, to code reader, 72. Signal processor system, 71, also has signal processor means to control signal processor system, 71, to record meter-monitor information of said message information, and to transfer recorded information to external communications network, 97.
Column 11 lines 12-14.	Code reader, 72, passes the received signals, with channel identifiers, to cable program controller and computer, 73.	Page 326 lines 16-18.	Code reader, 72, buffers and passes the received SPAM message information, with source mark information, to cable program controller and computer, 73.
Column 11 lines 15-17.	Cable program controller and computer, 73, is the central automatic control unit for the transmission facility.	Page 326 lines 19-20.	Cable program controller and computer, 73, is the central automatic control unit for the transmission station.
Column 11 lines 18-31.	The controller/computer, 73, has means for receiving input information from local input, 74, and from remote sources via telephone or other data transfer network, 98. Such input information might include the cable television system's complete programing schedule, with each discrete unit of programing identified with a unique program code (which in the case of advertising might be a purchase order number).	Page 326 line 23 to page 327 line 2.	Computer, 73, has capacity for maintaining records on the station's programming schedule and records on the status of operating apparatus. Computer, 73, has means for receiving input information from local input, 74, and from remote stations via telephone or other data transfer network, 98. Such input information can include the complete programming schedule of the station of Fig. 6, with each discrete unit of programming

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
	Such input information might also indicate when and where the cable head end facility should expect to receive the programing. Such input information might also indicate when and on which channel or channels the head end facility should transmit each program unit to cable field distribution system, 93.		identified by its own "program unit identification code" information. Such input information can indicate when and how the station should expect to receive each program unit, when and on which channel or channels and how the station should transmit the unit, what kind of programming the unit is--eg, conventional
Column 11 lines 32-37.	By means of the signals, with channel indicators, received from code reader, 72, controller/computer, 73, can determine what specific programming and programing unit has been received by each receiver, 53 through 62, and is passing in line on each individual wire to matrix switch, 75.	Page 327 line 35 to page 328 line 7.	Computer, 73, monitors incoming programming by means of the aforementioned dedicated decoders of signal processor system, 71. By means of the SPAM message information, with source mark information, received from code reader, 72, computer, 73, determines what specific program unit has been received by each receiver, 53 through 62, and is passing in line, via each distribution amplifier, 63 through 70, to matrix switch, 75.
Column 11 lines 38-43.	By comparing identification signals on the incoming programming with the programing schedule received earlier from local input, 74, and/or from a remote site via network, 98, controller/computer, 73, can determine when and on what channel or channels the head end facility should transmit the programing.	Page 328 lines 8-13. ²⁶	By comparing selected meter-monitor information of said message information with information of the programming schedule received earlier from input, 74, and/or network, 98, computer, 73, can determine, in a predetermined fashion, when and on what channel or channels the station of Fig. 6 should transmit the programming of each received program unit.
Column 11 lines 44-46.	Controller/computer, 73, has means for communicating control information with matrix switch, 75, and video recorder/players, 76 and 78.	Page 328 lines 14-17.	Computer, 73, has means for communicating control information with matrix switch, 75, and video recorders, 76 and 78, and can cause selected programming to be transmitted to field distribution system, 93, or recorded.
Column 11 lines 47-57.	If incoming programming is meant for immediate transmission, controller/computer, 73, instructs matrix switch, 75, to configure its switches so as to transfer incoming programming to the proper output channel. For example, if controller/computer, 73, determines that programming incoming via receiver, 53, should be transmitted immediately to the field distribution system, 93, via cable channel modulator, 87, controller/computer, 73, instructs matrix switch, 75, to configure its switches so as to transfer programming transmissions inputted from TV receiver, 53, to the output that leads to modulator, 87.	Page 328 line 18 to page 329 line 1.	Determining that particular incoming programming is scheduled for immediate retransmission can cause computer, 73, to cause matrix switch, 75, to configure its switches so as to transfer said incoming programming to a scheduled output channel. For example, computer, 73, receives a given SPAM message that contains given "program unit identification code" information and the added source mark information of said message identifies distribution amplifier, 63. Receiving said message causes computer, 73, to determine, in a predetermined fashion, that said "code" information matches particular preprogrammed schedule information of programming that is scheduled to be retransmitted immediately upon receipt to field distribution system, 93, via cable channel modulator, 87. In its preprogrammed fashion, so determining causes computer, 73, to cause matrix switch, 75, to configure its switches so as to transfer the programming transmission inputted (via distribution amplifier, 63) to matrix switch, 75, from TV receiver, 53, to that output of matrix switch, 75, that outputs to modulator, 87.
Column 11 lines 57-65	Similarly, if controller/computer, 73, determines that incoming programming should be recorded for delayed transmission, controller/	Page 329 line 23 to page 330	Determining that particular incoming programming is not scheduled for transmission can cause computer, 73, to cause station apparatus to discard

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
	computer, 73, selects a video recorder/player, 76 or 78, in a predetermined fashion, to record the incoming programming, instructs matrix switch, 75, to transfer the programming to the designated recorder/player, 76/78, and instructs the recorder/player, 76 or 78, to turn on and record the programming.	line 4.	the transmission of said programming. For example, computer, 73, receives a given SPAM message that contains given "program unit identification code" information and the added source mark information of said message identifies distribution amplifier, 69. Receiving said message causes computer, 73, to determine, in a predetermined fashion, that said "code" information matches no particular preprogrammed schedule information. In its preprogrammed fashion, so determining causes computer, 73, either to cause matrix switch, 75, to configure its switches so as to transfer the programming transmission inputted (via distribution amplifier, 69) to matrix switch, 75, from TV demodulator, 61, to no output of matrix switch, 75; or to cause a selected recorder, 76 or 78, to cease recording; or both.
Column 11 line 66 to column 12 line 8.	Recorder/players, 76 and 78, can communicate programming with each other through matrix switch, 75. If controller/ computer, 73, determines at any time that it is necessary to reorganize the order in which programming units are stored on either recorder/player or on both, controller/computer, 73, can use techniques for reorganizing files stored on multidisk units, which techniques are well known to computer operators, and order the execution of such techniques by passing appropriate instructions to of matrix switch, 75, and recorder/ players, 76 and 78.	Page 331 line 17 to page 334 line 6.	Computer, 73, has capacity for automatically organizing the locations of units of prerecorded programming on recording media such as magnetic video tapes loaded on a plurality of recorder/players to play according to a given schedule. For example, four spot commercials--program units Q, Y, W, and D--are loaded on 76 and 78. D and Q are recorded on the video tape loaded on recorder, 76, with D first. W and Y are recorded on the tape on recorder, 78, with W first. According to the schedule recorded at computer, 73, Q should play first on the cable channel modulated by cable channel modulator, 83; then subsequently Y and W should start to play simultaneously on the channels modulated by modulators, 83 and 87 respectively; then D should play on the channel modulated by modulator, 83, immediately after Y ends. Caused to organize the locations of said units to play according to said schedule, computer, 73, determines automatically, in a predetermined fashion, that units Q, Y and D should be recorded on the tape loaded on recorder, 76, with Q recorded first and D recorded immediately after Y. In a predetermined fashion, computer, 73, determines that insufficient available space exists on the tape on recorder, 76, to record Y immediately before D or on recorder, 78, to record D immediately after Y. So determining causes computer, 73, automatically to locate a place on the tape loaded on recorder, 78, that contains sufficient space for recording D.
Column 12 lines 8-12.	Were this head end facility equipped with automatic operating equipment well known in television studios, controller/computer, 73, could pass appropriate operating instructions to such equipment.	Page 359 lines 15-20. ²⁷	...receiving said message at computer, 73, causes particular SPAM decoder apparatus of computer, 73, (which apparatus is analogous to SPAM- controller, 205C, at microcomputer, 205, above and is not distinguished from computer, 73, hereinafter) to execute particular controlled functions.
Column 12 lines	Controller/computer, 73, monitors the operation of the head end facility	Page 327 lines	Computer, 73, monitors the operation of the head end station by means

13-25.	by means of TV signal decoders, 77, 79, 80, 84, and 88, each of which are shown in detail in Fig. 2A. Controller/computer, 73, has means to communicate control information with each decoder, 77, 79, 80, 84, and 88, to tell each how to operate and how and where to look for signals and to communicate other information. (This particular embodiment could be expanded to include a decrypter, such as decrypter 10 in Fig. 1, in signals-only line between each decoder, 77, 79, 80, 84, and 88, and controller/computer, 73.)	13-23.	of TV signal decoders, 77, 79, 80, 84, and 88, each of which are shown in detail in Fig. 2A. Computer, 73, has means to communicate control information with each decoder, 77, 79, 80, 84, and 88, to instruct each how to operate and how and where to search for SPAM information. (The control system of the station of Fig. 6 may be reconfigured to have the signal processor of system, 71, control said decoders, 77, 79, 80, 84, and 88, if decryption of encrypted SPAM message information is required at said decoders.)
Column 12 lines 24-26.	Decoders, 80, 84, and 88, inform controller/computer, 73, what programming is passing on each cable channel and what signals the programming contains.	Page 327 lines 24-26.	Computer, 73, monitors outgoing programming by means of decoders, 80, 84, and 88. By decoders, 80, 84, and 88, to select and transfer SPAM meter-monitor information....
Column 12 lines 26-34.	Decoders, 77 and 79, inform controller/computer, 73, what specific programming is loaded on recorder/players, 76 and 78 respectively, and what signals it contains. (Among other signals, a program unit could contain signals that would inform controller/computer, 73, of the distance to the beginning and end of the program unit which signals would facilitate operation of recorder/ players such as 76 and 78.)	Page 330 line 5 to page 331 line 16.	Computer, 73, has capacity for determining what programming is prerecorded on the magnetic tapes (or other recording media) loaded on the recorders, 76 and 78, and capacity for positioning the start points (or other selected points) of program units at the play heads of said recorders. Whenever programming is played on recorder, 76 or 78, decoder, 77 or 79 respectively, detects SPAM information embedded in the prerecorded programming played at the play heads of recorder, 76 or 78, and transmits said SPAM information to computer, 73. Said SPAM information can include not only "program unit identification code" information but also information regarding of the distance from the point on the tape at which a given SPAM message is embedded to the point on the tape where the program unit begins and ends (or to any other selected point). To position the start point (or another selected point) of a given program unit at the play heads of a given recorder, 76, computer, 73, instructs switch, 75, to configure its switches so as to transfer the transmission input from said recorder, 76, to no output. Then by instructing recorder, 76, to play and decoder, 77, to detect SPAM information in a particular location or locations, computer, 73, causes decoder, 77, to detect and transfer to computer, 73, said program unit and distance information. Receiving said information causes computer, 73, to cause recorder, 76, to stop playing; to analyze said distance information in a predetermined fashion; and to compute the precise time required to rewind to reach the start of the program unit or to move fast forward to reach the end. Then automatically, computer, 73, causes said recorder, 76, first, to start rewinding or moving fast forward then to stop after the precise time elapses. (Such distance information can be embedded as SPAM message information segment information anywhere in the programming that SPAM information can be embedded and need not repeat continuously—one embedded signal word is sufficient for this method to work. But a method wherein only one instance of distance information is

Column 12 lines 35-44.	The cable head end facility also contains signal strippers, 81, 85, and 89, of which models exist well known in the art, that controller/computer, 73, can instruct to remove signals from programming as required, and signal generators, 82, 86, and 90, also well known in the art, that controller/ computer, 73, can instruct to add signals to programming as required. At each point, 81, 85, and 89, there may be single or multiple strippers. At each point, 82, 86, and 90, there may be single or multiple generators.		embedded in any given program unit of programming has the disadvantage of causing too much apparatus at too many stations to spend too much time searching for said instance. In the preferred embodiment, distance information is embedded in the relevant normal transmission location of its programming and occurs periodically throughout a program unit with increasing frequency as the closeness of the start or end of the programming approaches and with one instance, in television programming, occurring on the first and fourth frames and the last two frames of the programming.)
Column 12 lines 45-56.	Beyond channel combining system and multiplexer, 92, amplifier, 94, transmits programming to signal processor, 71, and signal processor, 96, which permits both apparatus to monitor and record all the programming transmitted by the cable television system head end facility to field distribution system, 93. Such records can provide automatically for each channel the information that the Federal Communications Commission requires broadcast station operators to maintain as station logs. Signal processors, 71 and 96, can transmit such records of programming to remote sites via telephone or other data transfer networks, 97 and 99 respectively.	Page 354 lines 18-34.	Fig. 6 shows signal strippers, 81, 85, and 89, of which models exist well known in the art, that computer, 73, can cause to remove SPAM information from programming as required, and signal generators, 82, 86, and 90, also well known in the art, that computer, 73, can cause to embed SPAM information as required. Said generators, 82, 86, and 90, have capacity for receiving control information and programming in a transmission from computer, 73, and distinguishing, in a predetermined fashion, said control information from said programming. Said strippers, 81, 85, and 89, and generators, 82, 86, and 90, have capacity for stripping or embedding SPAM information at as little as one portion of one line of one frame of a television transmission or as much as every line of every frame and capacity to strip or insert SPAM information on a given frame at multiple, noncontiguous locations.
		Page 337 lines 1-24.	Fig. 6 shows particular signal processor system monitoring apparatus associated with the intermediate station of Fig. 6. In field distribution system, 93, amplifier, 94, inputs programming transmissions to signal processor system, 71, (where said transmissions are inputted to one alternate contact of the switch, 1, of the signal processor of said system, 71), and amplifier, 95, inputs programming transmissions to signal processor, 96, which permits both signal processor apparatus to monitor all programming transmitted by the cable television system head end station to field distribution system, 93, in the fashion of the signal processor, 200, of Fig. 3 in example #5. By recording all different received "program unit identification code" information in the fashion described above, said signal processor apparatus can automatically record, for each transmission channel of the station of Fig. 6, information, for example, that the U. S. Federal Communications Commission requires broadcast station operators to maintain as station logs. And said signal processor apparatus can transmit such records of programming to remote sites via telephone or other data transfer networks, 97 and 99 respectively. In this fashion, said signal processor apparatus can automatically provide their contained records to one or more remote independent auditor stations.

Column 12 lines 57-67.	This particular embodiment describes a transmission facility transmitting only television programming. The facility could also process and transmit radio programming and other electronic data according to the methods described here by adding radio decoder paths and other signal decoder paths, as shown in Figures 2B and 2C respectively, to signal processors, 71 and 96, and decoders, 77, 79, 80, 84, and 88. Likewise, these methods are also applicable in a facility that transmits only a single channel of radio or television programming.	Page 324 lines 8-17. ²⁸	The signal processing apparatus outlined in Figs. 2, 2A, 2B, 2C, and 2D, and their variants as appropriate, can be used to automate the operations of intermediate transmission stations that receive and retransmit programming. The stations so automated may transmit any form of electronically transmitted programming, including television, radio, print, data, and combined medium programming and may range in scale of operation from wireless broadcast stations that transmit a single programming transmission to cable systems that cablecast many channels simultaneously.
Column 12 line 68 to column 13 line 17.	Methods for Governing the Reception of Programming Figures 4A through 4E illustrate methods for governing the reception of programming and the use of signal processor apparatus in these methods. All of these methods involve the use of one or more devices, of which various models exist well known in the art, for the decryption of programming transmissions and/or one or more other means for interrupting programming transmissions, also well known in the art, which may be as simple as a switch and which may have means to interrupt programming by generating noise which noise may be an overlay of another audio and/or video transmission. Figure 4A shows a signal processor, 100, and a programming decrypter and/or interrupt means, 101, each of which receives the same transmission of programming. The devices, 100 and 101, may receive one channel of programming or multiple channels.	Page 279 line 4 to page 280 line 35. ²⁹	In the prior art, various means and methods exist for regulating the reception and use of electronically transmitted programming. Various scrambling means are well known in the art for scrambling, usually the video portion of analogue television transmissions in such a fashion that only subscriber stations with appropriate descrambling means have capacity to tune suitably to the television transmissions and display the transmitted television image information. Encryption/decryption means and methods, well known in the art, can regulate the reception and use of, for example, digital video and audio television transmissions, digital audio radio and phonograph transmissions, digital broadcast print transmission, and digital data communications. Other techniques, well known in the art, involve controlling interrupt means that may be as simple as on/off switches to interrupt or disconnect programming transmissions at stations that lack authorizing information or are determined in other fashions not to be duly authorized. Still other techniques, also well known in the art, involve controlling jamming means that spoil transmitted programming at stations that lack authorizing information or are determined not to be duly authorized, thereby degrading the usefulness of said programming. Such other techniques include, for example, inserting so-called "noise" into the transmitted programming which noise may be, for example, overlays of one or more separate transmissions.
Column 13 lines 17-20.	The signals that enable the decrypter/interrupter, 101, to decrypt and/or transfer programming uninterrupted may be embedded in the programming or may be elsewhere.	Page 297 lines 20-29. ³⁰	Subsequently, but still in the interval between said commence-enabling time and said 8:30 PM time, said program originating studio embeds in the audio portion and transmits a particular SPAM message that consists of a "01" header, execution segment information that matches said enable-WSW- programming information, particular meter-monitor information, particular 1st-stage-enable-WSW-program instructions as the information segment information, and an end of file signal. (Hereinafter said message is called the "1st-WSW-program-enabling-message (#7).")
Column 13 lines 20-24.	Signal processor, 100, identifies, evaluates, possibly decrypts, and passes a signal or signals to decrypter/interrupter, 101, either at the time	Page 290 lines 26-30. ³¹	... causes the oscillator, 6, then to cause switch, 1, and mixer, 3, to select information of a particular master cable control channel (that may or may

Column 13 lines 33-53.	<p>Figure 4A also shows local input, 102, with means for generating and transmitting signals to signal processor, 00. Local input, 102, is intended to permit a person at a local receiving site that is prevented, by any means, from receiving programming to instruct signal processor, 100, that the site wants to be enabled to receive the programming. Local input, 102, may also serve other purposes. Local input, 102, may convey a continuous signal or an occasional signal or a one-time-only signal. It may be activated by one or more switches or buttons or combinations. It may be a computer acting in a predetermined fashion. The signal may be input to signal processor, 100, as described in Figure 1, at buffer/comparator, 8, or signal processor or monitor, 12, or buffer/comparator, 14.</p> <p>In the preferred embodiment, local input, 102, inputs a one-time signal to signal processor, 100, at buffer/ comparator, 8, and transmits information in a digital code signal which information is input to local input, 102, in an alphanumeric form manually by means of buttons.</p>	Page 288 lines 1-20.	<p>Finally, Fig. 4 shows local input, 225, well known in the art, which has means for generating and transmitting control information to controller, 20, of signal processor, 100. The function of local input, 225, is to provide means whereby a subscriber may input information to the signal processor of his subscriber station, thereby controlling the functioning of his personal signal processor system is specific predetermined fashions that are described more fully below. In the preferred embodiment, local input, 225, is actuated by keys that are depressed manually by the subscriber in the fashion of the keys of a so-called touch- tone telephone or the keys of a typewriter (or microcomputer) keyboard. As Fig. 4 shows, microcomputer, 205, also has capacity for inputting control information to microcomputer, 205, via decoder, 203, and in the preferred embodiment, microcomputer, 205, may also automatically substitute for local control, 225, in predetermined fashions in inputting control information to said controller, 20, on the basis of preprogrammed instructions and information previously inputted to said microcomputer, 205.</p>
Column 13 lines 54-60.	<p>Figures 4B and 4C illustrate various alternative ways that signals may be input to the signal processor, 100, 103, or 106 as applicable. The fundamental point is that signals may be received in a manner that requires decryption and/or transmission by a decryptor/interruptor, 104, before they reach the signal processor, as with signal processor 103 in Figure 4B,</p>	Page 299 line 22 to page 300 line 16.	<p>...thereby causing said decryptor, 224, to receive the information of said video portion (said information being, as explained above, encrypted digital video), to decrypt said information, and to transfer decrypted information of said video portion to matrix switch, 258. Automatically, controller, 20, causes matrix switch, 258, to transfer the information inputted from decryptor, 224, to the output that that outputs to signal processor, 200, thereby causing signal processor, 200, to receive said information at the aforementioned third alternate contact of switch, 1. Automatically, controller, 20, clears all information of any prior SPAM message from decoder, 30; causes mixer, 3, and the filter, 31, and the modulator, 32, of decoder, 30, to input said information to the digital detector, 38, without any modification (switch, 1, is already connected to said third contact); and causes the control processor, 39J, of decoder, 30, to commence accepting SPAM message information from EOFs valve, 39F, and record all received SPAM message information in a predetermined fashion at the RAM associated with said control processor, 39J, until an interrupt signal of EOFs-signal-detected information is received and then to process said EOFs-signal-detected information in a predetermined fashion.</p> <p>In due course, but still before said 8:30 PM time, said program originating studio embeds in the video portion and transmits particular SPAM check information that is not a SPAM message and consists only of a particular check sequence of binary information followed by an end of file signal. (Hereinafter said SPAM check information is called the "1st-WSW-decryption-check (#7).")</p>

Column 13 line 60 to column 14 line 1.	<p>or they may not, as with signal processor 100 in Figure 4A, or some combination, as with signal processor 106 in Figure 4C.</p> <p>However, Figures 4A, 4B, and 4C do not fully illustrate this point because these figures do not reveal that the question of the need for decryption prior to reaching the signal processor depends, among other things, on where the signal or signals are placed in the incoming transmission. A decrypter does not necessarily decrypt the entire transmission.</p>	Page 297 lines 30-33.	In the fashions described above, so transmitting said SPAM message causes signal processor, 200, at the digital detector, 38, of decoder, 30, to detect the information of said message and at the control processor, 39J,
Column 14 lines 1-4.	<p>Encrypted transmissions may be only partially encrypted. For example, only the video portion of the transmission may be encrypted. The audio portion may remain unencrypted.</p>	Page 288 line 33 to page 289 line 4.	<p>... Prior to being transmitted, the digital video information is doubly encrypted, by means of particular cipher algorithms A and B and cipher keys Aa and Ba, in such a way that said information requires decryption at subscriber stations in the fashion described below. The digital audio is transmitted in the clear.</p>
Column 14 lines 4-9.	<p>In such a circumstance, a connection such as that shown in Figure 4B could pass unencrypted signals to signal processor 103, while passing a transmission unsuitable for satisfactory viewing, if the signals were placed in the audio portion of the overall transmission.</p>	Page 297 lines 20-33.	<p>Subsequently, but still in the interval between said commence-enabling time and said 8:30 PM time, said program originating studio embeds in the audio portion and transmits a particular SPAM message that consists of a "01" header, execution segment information that matches said enable-WSW-programming information, particular meter-monitor information, particular 1st-stage-enable-WSW-program instructions as the information segment information, and an end of file signal. (Hereinafter said message is called the "1st-WSW-program-enabling-message (#7).")</p> <p>In the fashions described above, so transmitting said SPAM message causes signal processor, 200, at the digital detector, 38, of decoder, 30, to detect the information of said message and at the control processor, 39J,</p>
Column 14 lines 10-27.	<p>Figure 4C illustrates a configuration that permits a method that provides a signal or signals to signal processor, 06, prior to decryption which signal or signals enables decryptor/interruptor, 107, to decrypt and/or pass programming transmissions it receives then signal processor, 106, searches in a predetermined fashion for a second signal or set of signals in the decrypted output of decryptor/interruptor, 107. If this second signal or set of signals fails to appear in the form or forms and place or places and time or times that signal processor, 106, expects, signal processor, 106, can respond in a predetermined fashion and generate and record in digital recorder, 16 (referring to Fig. 1), information that reports this fact in a predetermined fashion and/or transfer this information immediately to a remote site by telephone means and/or generate and transmit to decryptor/interruptor, 107, instructions that disable decryptor/interruptor, 107.</p>	Page 293 line 20 to page 294 line 27. ³⁴	<p>... for example, the RAM of controller, 20; the RAM of controller, 12; the RAM associated with the control processor, 39J, of decoder, 203; the RAM associated with the processor, 39B, of the decoder, 30, of signal processor, 200; etc.) A match indicates that said sixteen contiguous bit locations that hold preprogrammed SPAM operating information are preprogrammed with properly. A match occurs at the station of Fig 4. (Simultaneously other stations compare information of other selected information of bit locations that contain information of said enable-CC13 instructions with information of other local bit locations that hold preprogrammed SPAM operating information. At each station where a match fails to occur--which suggests that the preprogrammed SPAM operating information of said station has been tampered with in an unauthorized fashion--not resulting in a match causes the controller, 20, of said station to cause all information of said local-cable-enabling-message (#7) to be erased from all memory of said station except for a particular portion of said enable-CC13 instructions loaded at the RAM of said controller, 20, then to execute the information of said portion as</p>

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
			information of a so-called "machine language job". Erasing said information from memory prevents the apparatus of said station from decrypting the encrypted information of said "Wall Street Week" program, and executing said portion causes said controller, 20, to cause the auto dialer, 24, and telephone connection, 22, to establish telephone communications with a particular predetermined remote station, in the fashion described above in "Operating Signal Processor Systems ... Signal Record Transfer," and causes controller, 20, then to transmit information of the aforementioned unique digital code at ROM, 21, that identifies said station and signal processor, 200, of said station uniquely as well as particular predetermined appearance-of-tampering information. Transmitting said unique code and appearance-of-tampering information enables apparatus at said remote station to identify said remote station. If telephone communications are not established with said remote station in a predetermined fashion and/or within a predetermined time interval, executing said portion causes said controller, 20, to erase all preprogrammable RAM and EPROM of the signal processing apparatus at said station, thereby disabling said apparatus.)
Column 14 lines 28-32.	Figure 4D shows that a multi-stage decryption/interruption process may be used in which transmissions must be processed by one or more additional decryptor/interruptors, 111, that follow decryptor/interruptor, 110.	Page 288 line 33 to page 289 line 3. ³⁵	Prior to being transmitted, the digital video information is doubly encrypted, by means of particular cipher algorithms A and B and cipher keys Aa and Ba, in such a way that said information requires decryption at subscriber stations in the fashion described below.
Column 14 lines 33-46.	Figure 4E illustrates that the signal processor, 112, can monitor multiple channels and pass instructions to multiple decryptor/interruptors, each of which processes fewer channels than the multiple channels processed by signal processor, 112. Figure 4E illustrates how signals transmitted on one channel can govern the decryption and/or transfer of another channel. Signal processor, 112, receives, evaluates, and processes a multiple channel transmission from cable transmission facility, 113. Cable converter box, 114, of which many types are now available, with means for informing signal processor, 112, which channel of programming it is transferring, receives the same multi-channel transmission and transfers one channel to decryptor/interruptor, 115.	Page 286 lines 9-17. ³⁶	The subscriber station of Fig. 4 has capacity for receiving wireless television programming transmissions at a conventional antenna, 199, and a multi-channel cable transmission at converter boxes, 201 and 222. Said boxes, 201 and 222, are conventional cable converter boxes with capacity, well known in the art, for receiving information of a selected channel of a multiplexed multi-channel transmission and converting the selected information to a given output frequency.
Column 14 lines 46-50.	The signal or signals necessary for the decryption of the channel that box, 114, passes to decryptor/interruptor, 115, in this case, is not located in the channel transmission.	Page 291 lines 9-20, including "master control channel" at line 18.	In the interval between said commence-enabling time and said 8:30 PM time, said head end is caused, in a predetermined fashion, to transmit a particular enabling SPAM message that consists of a "01" header, execution segment information that matches said enable-next-program-on-CC13 information, particular meter-monitor information, information segment information of particular enable-CC13 instructions and particular enable-WSW instructions that include particular

Reference	Language	Reference	Language

	programming transmission satisfactorily.		suggests that the preprogrammed SPAM operating information of said station may have been tampered with—....
Column 15 lines 8-19.	Figure 4E also illustrates how it may be necessary to decrypt a programming transmission on one channel in order to identify and process correctly the programming transmitted on another. In Fig. 4E, the signal or signals needed to operate decryptor/interruptor, 115, correctly may be on a separate channel of programming that is, itself, encrypted in transmission. Signal processor, 112, can transfer the correct signal or signals only if cable converter box, 117, is tuned to the proper channel and decryptor/interruptor, 118, can transfer a correctly decrypted transmission to signal processor, 112, for processing.	Page 295 line 30 to page 296 line 8. ⁴⁰	Automatically, controller, 20, selects information of cipher key Ca from among the information of said portion; transfers said cipher key information to decryptor, 107; and causes decryptor, 107, to commence decrypting its received audio information, using said key information and selected decryption cipher algorithm C, and outputting decrypted information of the audio portion of the "Wall Street Week" program transmission to matrix switch, 258. Automatically, controller, 20, causes matrix switch, 258, to transfer the information inputted from decryptor, 107, to the output that that outputs to signal processor, 200, thereby causing signal processor, 200, to receive said information at a particular third alternate contact of switch, 1, (that is not shown in Fig. 2).
Column 15 lines 20-25.	In any of the cases illustrated in Figures 4A through 4E, signal processors, 100, 103, 106, 109, and 112, could also operate in a predetermined fashion and telephone a remote site to get an additional signal or signals necessary for the proper decryption and/or transfer of incoming programming transmissions.	Page 311 line 33 to page 312 line 8.	And for example, determining that a local station is not preprogrammed properly and/or that decryption, stripping, and/or signal generating apparatus are not functioning correctly may cause apparatus of said station to perform other steps of disabling and/or communicating—eg., the local apparatus may disable local apparatus selectively and only partially by, for example, preventing a decoder, 203, from processing embedded SPAM combining synch commands and may interrogate remote station apparatus, by telephone, for cipher key and/or cipher algorithm instructions and information.
Column 15 lines 26-30.	<u>Methods for Monitoring Reception and Operation</u> Figure 5 illustrates methods for monitoring reception and operation which methods can be used to gather statistics on programming usage and associated uses of other data transmissions and equipment.	Page 312 line 33 to page 313 line 15.	Fig. 5 illustrates means and methods for monitoring receiver station reception and use of programming and modes of receiver station operation and exemplifies one embodiment of a subscriber station that is preconfigured and preprogrammed to collect monitor information. The means and methods facilitate the collection of statistics that identify not only what programming is received and displayed at given subscriber stations but also, for example, which local apparatus receives programming and which displays programming, how received programming is processed, what local apparatus is controlled in the course of processing and how, what locally preprogrammed data is processed by or with the received programming, which local apparatus is caused to transmit programming, etc. Efficient collection of such statistics enables suppliers of programming and of subscriber station apparatus to identify which programming subscribers demand and how subscribers use their programming and apparatus.
Column 15 lines 30-32.	Such statistics are necessary, for example, in the development of television program ratings.	Page 162 lines 30-34.	First, example #3 focuses on selected subscriber stations where signal processing apparatus and methods are used to collect monitor information

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
Column 15 lines 33-44.	Figure 5 shows two conventional TV sets, 132 and 144, a conventional video cassette recorder, 135, a conventional videodisc player, 137, a conventional radio, 141, a conventional microcomputer, 142, a conventional data printer, 146, and a television set, 148, that is capable of displaying two different television programming transmissions at once. This is only a representative group of equipment. Many other types of television and radio players and recorders could be included in Figure 5. Except for the videodisc player which neither records nor displays programming or other data, each unit has an appropriate associated signal decoder.	Page 313 line 16-23+.	for so-called "program ratings" (such as so-called "Nielsen ratings") that estimate the sizes of television (or radio) program audiences. Fig. 5 shows a variety of input apparatus with capacity for inputting programming (including SPAM information) selectively, via matrix switch, 258, to apparatus of the subscriber station of Fig. 5, intermediate apparatus with capacity for processing and/or recording inputted programming selectively, and output apparatus for displaying or otherwise outputting programming selectively to human senses. ...
Column 15 lines 44-51.	Each decoder is likely to be located physically inside its associated player/ recorder unit. Each is located at a point in the associated unit's circuitry where it receives every embedded signal on the programming channel or data channel to which the unit is tuned for which signal the decoder is programmed in a predetermined fashion to search.	Page 314 lines 31-33.	At other output system, 261, is other decoder, 286. Each decoder is likely to be located physically inside the unit of its associated intermediate or output apparatus.
Column 15 lines 52-56.	If a unit like the microcomputer can receive transmissions from more than one source or of more than one kind--television, radio, or other--it will have sufficient apparatus to monitor every channel and kind of transmission it can receive.	Page 313 line 16-23+.	See reference above.
Column 15 line 57 to column 16 line 2.	The signals for which the decoders are monitoring are likely to be unique digital codes that may identify each programming or data unit received and the source of each. They may identify networks, broadcast stations, channels on cable systems, and possibly times of transmission. They may convey unique identifier codes for each program or commercial. In the case of data transmitted to the micro- computer, they may be unique codes that identify the source and suppliers of the data. In the case of data received at the printer, they may identify publications, articles, publishers, distributors, advertisements, etc. The decoders, 31, 136, 138, 143, 145, 147, 149, and 150, may search for many types of codes, and the types described here provide only examples.	Page 317 lines 2-6.	If a given intermediate or output apparatus can receive transmissions from more than one source or of more than one kind--television, radio, or other--it will have sufficient apparatus to monitor every channel and kind of transmission it can receive.
Column 16 lines 3-24.	In Figure 5, each decoder receives every relevant signal received by its associated player or recorder unit. For example, TV set, 131, may receive programming from many sources including cable converter box, 133, video cassette recorder, 135, and videodisc player, 137. In every programming unit played on TV set, 132, TV decoder, 131, receives every signal for which it is instructed to search in a predetermined	Page 49 line 20 to page 50 line 25.	...Said constant number is the smallest number of bits capable of representing the binary value of the total number of appropriate addressed apparatus and controlled function combinations. And each appropriate combination is assigned a unique binary value within the range of binary numbers thus defined. Meter-monitor segments contain meter information and/or monitor

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
Column 16 lines 25-47.	<p>fashion and transfers the signals to signal processor, 130, which has means to identify the source decoder from which each signal that it receives comes. On all programming recorded by video cassette recorder, 135, decoder, 136, receives every relevant signal and transfers such signals to signal processor 130. Radio signal decoder, 138, operates similarly for radio, 141. Other signal decoder, 143, for microcomputer 142. TV signal decoder, 145, for TV set, 144 (which may receive programming inputs and associated signals generated or transferred by microcomputer, 142). Other signal decoder, 147, for printer 146. And TV signal decoders, 150 and 149, for each channel of programming received and displayed by multi-picture TV set, 148.</p>		<p>information. Examples of categories of such information include: meter instructions that instruct subscriber station meter apparatus to record particular meter-monitor segment information and maintain meter records of said information; origins of transmissions (eg., network source stations, broadcast stations, cable head end stations); dates and times; unique identifier codes for each program unit (including commercials); codes that identify uniquely each combining in a given combined medium program unit; codes that identify the subject matter of a program unit; unique codes for programming (other than programming identified by program unit codes) whose use obligates users to make payments (eg., royalties and residuals); and unique codes that identify the sources and suppliers of computer data. The categories listed here provide only examples. Other types of information can exist in meter information and/or in monitor information, as will become apparent....</p>
Column 16 lines 25-47.	<p>One particular advantage of these methods for monitoring programming is that, by locating the identifier signals in the audio and/or video and/or other parts of the programming that are conventionally recorded by, for example, conventional video cassette recorders, these methods provide techniques for gathering statistics on what is recorded on video cassette recorders and on how people replay such recordings. For example, a person might instruct video cassette recorder, 135, automatically to record the NBC Network Nightly News as broadcast over station WNBC in New York City. Recorder, 135, might receive the programming over Manhattan Cable TV channel 4 and record the programming from 7:00 PM to 7:30 PM on the evening of July 15, 1985. Each discrete bit of this information could be conveyed to recorder, 135, in a signal unit or units in the programming so received and recorded. Decoder, 136, would identify these signals and transfer them to signal processor, 130. Subsequently, the person might play the recorded programming on TV set, 132, from 10:45 PM to 11:15 PM the same evening. This time, TV signal decoder, 31, identifies the embedded signals and transfers them to signal processor, 131.</p>	Page 319 line 23 to page 320 line 35.	<p>One particular advantage of these methods for monitoring programming is that, by embedding the SPAM information in the audio and/or video and/or other parts of the programming that are conventionally recorded by, for example, conventional video cassette recorders, these methods provide techniques for gathering statistics on what is recorded, for example, on video and audio cassette recorders and on how people replay such recordings. For example, a subscriber might instruct video recorder/player, 217, automatically to record the NBC Network Nightly News as broadcast over station WNBC in New York City. Recorder, 217, might receive the programming over Manhattan Cable TV channel 4 and record the programming at the time of original broadcast transmission—from 7:00 PM to 7:30 PM on the evening of July 15, 1985. Each discrete bit of this information could be transmitted to the subscriber station of Fig. 5 in meter-monitor information (of a SPAM command with an appropriate execution segment such as information of the pseudo command) embedded in the transmitted programming. So embedding and transmitting said meter-monitor information would cause recorder, 217, to record said information. In addition, decoder, 218, would detect said information and transfer said information to signal processor, 200, together with appropriate source mark information, but no decoder apparatus associated with any of the aforementioned output apparatus would detect said information, causing said signal processor, 200, in a predetermined fashion to record a signal record of programming recorded at recorder,</p>

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
			217. (Simultaneously, the information of said programming is being displayed at the monitors, 202M, of other subscriber stations that are tuned to the frequency of said News as broadcast; decoders, 145, associated with said monitors, 202M, are detecting said embedded meter-monitor information and transmitting said information to the signal processors, 200, of said stations; and said signal processors, 200, are recording signal records of programming displayed at said monitors, 202M.) Subsequently, the subscriber might play back the recorded programming and view said programming on TV monitor, 202M, from 10:45 PM to 11:15 PM the same evening. So playing back and transmitting the recorded programming to monitor, 202M, would cause TV signal decoder, 145, to detect said meter-monitor information and transfer said information, together with appropriate source mark information, to signal processor, 131, causing said signal processor, 200, to record a signal record of said information together with date and time information of said 10:45 PM to 11:15 PM the same evening selected from the clock, 18, of signal processor, 200.
Column 16 lines 47-49.	Prerecorded video cassettes and videodiscs could also contain unique embedded codes that would identify their usage	Page 321 lines 1-6.	Prerecorded, commercially distributed video and audio tapes, videodiscs, so-called "compact discs" of audio, and so-called "CD ROM" discs of data can also contain unique codes, embedded in the prerecorded programming, that identify the use and usage of said programming when said tapes or discs are played.
Column 16 lines 49-50.	(and could also transfer instructions to other external equipment).	Page 321 line 20. ⁴¹	...to detect said embedded messages at amplifier, 213,....
Column 16 lines 51-56.	Signal processor, 130, would probably receive these signals from decoders, 131, 136, 138, 143, 145, 147, 149, and 150) at its buffer/comparator unit, 14 (referring to Fig. 1), in a predetermined fashion that would permit signal processor, 130, to identify which decoder the individual signals come from	Page 315 lines 6-11. ⁴²	Fig. 5 shows each decoder as having capacity for transferring monitor information to signal processor, 200, by bus communications means. Said information is received (and processed) at signal processor, 200, by the onboard controller, 14A, which controls the communications of said bus means in a fashion well known in the art.
Column 16 line 56 to column 17 line 9.	and, in a predetermined fashion, create a signal string by appending digital information to the received signal which information might identify the individual decoder, 131, 136, 138, 143, 145, 147, 149, or 150 and the time of receipt at signal processor, 130. To minimize the use of data recorder, 16, buffer/comparator, 14, may evaluate signals in a predetermined fashion and discard some signals rather than passing them to the recorder, 16. It may compare each signal from a given source such as decoder, 131, with other signals received earlier from the same source. It may only count incoming duplicate signals or it may append a time code to the end of the basic signal string formed around the first received signal and alter this time designation each time	Page 322 line 30-35. ⁴³	...to detect, process, and transmit monitor information of said messages to onboard controller, 14A, that is identical to said 1st monitor information (#3) and 2nd monitor information (#3) except that the source mark information identifies decoder, 282, rather than decoder, 203.

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language

	a new duplicate signal is identified so that the time code identifies the time of receipt of the last duplicate signal. Whatever method is used, the buffer/comparator, 14, may discard all duplicate signals received. At a time when buffer/comparator, 14, determines in a predetermined fashion that it will receive no further duplicate signals, it transfers the full signal string to recorder, 16.		
Column 17 lines 10-24.	Signal divider, 139, illustrates another type of monitoring that signal processing apparatus and methods can facilitate. Signal divider, 139, monitors the use of signals rather than the use of programming. Every instruction or information signal transmitted from processor, 140, to microcomputer, 142, is also transmitted to signal processor, 130, to be handled, recorded, and transmitted to a remote site with all other monitor information. In a predetermined fashion, signal processor, 130, identifies and marks the source of signals as coming from a device, 139, monitoring signal usage rather than programming usage and viewership. In this fashion, besides facilitating data gathering on how programming is used, signal processing apparatus and methods also permit the evaluation of how equipment is used. (For simplicity, Figure 5 has focused only on methods whereby data is gathered from signal decoders remote from signal processor, 130. Figure 5 has not included control information connections between signal processor, 130, and the remote decoders which would permit signal decoder, 130, to alter the methods of operation of said remote decoders. Such control information connections are included in signal processing apparatus and methods.)	Page 322 lines 28 to 35. ⁴⁴	Accordingly, transmitting said messages will also cause the decoder associated with tuner, 215-- decoder, 282--to detect, process, and transmit monitor information of said messages to onboard controller, 14A, that is identical to said 1st monitor information (#3) and 2nd monitor information (#3) except that the source mark information identifies decoder, 282, rather than decoder, 203.
Column 17 lines 25-33.	Methods for Governing or Influencing the Operation of Equipment that is External to Conventional Television and Radio Sets by Passing Instruction and Information Signals that are Embedded in Television and Radio Programming Transmissions to Such External Equipment Signal processor apparatus have the ability to identify instruction and information signals in one or more inputted television and radio programming transmissions,	Page 39 lines 14-21.	As Fig. 2D shows, controller, 20, has capacity to control all decoder apparatus, 27, 28, 29, 30, and 40. Controller, 20, has capacity to preprogram (or reprogram) all said decoder apparatus, 27, 28, 29, 30, and 40, and thereby controls the fashions of detecting, correcting, converting, modifying, identifying, transferring, and other functioning of said decoders.
Column 17 lines 34-41.		Page 15 lines 7-32.	In the present invention, particular signal processing apparatus (hereinafter called the "signal processor") detect signals and, in accordance with instructions in the signals and preprogramming in the signal processor, decrypt and/or record and/or control station apparatus by means of the signals and/or discard the signals. The apparatus includes one or more devices that can selectively scan transmission frequencies as directed and, separately, capacity to receive signals from one or more devices that continuously monitor selected frequencies. The frequencies may convey television, radio, or other programming transmissions. The input transmissions may be received by means of antennas or from hard-wire connections. The scanners/switches, working in parallel or series or combinations, transfer the transmissions to receiver/decoder/detectors that identify signals encoded in programming transmissions and convert the encoded signals to digital information; decryptors that may convert the received information, in part or in whole, to other digital information according to preset methods or patterns; and one or more

			processor/monitors and/or buffer/comparators that organize and transfer the information stream. The processors and buffers can have inputs from each of the receiver/detector lines and evaluate information continuously. From the processors and buffers, the signals may be transferred to external equipment such as computers, videotape recorders and players, etc.
Column 17 lines 42-44.	identify and discriminate among one or more pieces of external equipment to which such signals are addressed, and transfer such signals to such equipment as directed.	Page 31 lines 14-18.	If a signal or signals are to be transferred externally, in a predetermined fashion controller, 12, identifies the external apparatus to which the signal or signals are addressed and transfers them to the appropriate port or ports for external transmission.
Column 17 lines 45-46.	This permits many valuable techniques for facilitating the operation of such external equipment.	Page 390 lines 26-29.	The signal processing apparatus outlined in Figs. 2, 2A, 2B, 2C, and 2D, and their variants as appropriate, can be used to automate the operations of ultimate receiver stations in varieties of ways.
Column 17 lines 47-53.	Figure 6 illustrates one possible configuration of equipment in a home or office or other television and/or radio receiving site. Consideration of Figure 6 is facilitated by consideration, first, of individual examples of the types of co-ordinated presentations that the signal apparatus and methods described here can permit.	Page 390 lines 30-35.	Fig. 7 exemplifies one embodiment of an ultimate receiver station; is a subscriber station in the field distribution system, 93, of the intermediate transmission station of Fig. 6; and may be a home, an office, a theater, a hotel, or any other station where programming such as television or radio is displayed to persons.
Column 17 line 54.	Governing the Home or Office Environment	Generally, page 396 line 30 to page 406 line 31.	<i>Length of passage precludes inclusion here.</i>
Column 17 lines 55-62.	Figure 6A illustrates a method for governing a home or office environment. One or more channels of television programming transmissions inputted to signal processor, 200, and cable converter box, 201, may contain signals intended for microcomputer, 205, which signals convey information on local weather conditions. Such signals might include current outside temperature and barometric readings. They might include forecast data.	Page 396 line 31 to page 397 line 7.	Fig. 7A illustrates methods for regulating automatically the environment of subscriber stations such as homes and offices. Particular SPAM regulating messages are embedded in one or more television program channels that are inputted to signal processor, 200, and cable converter box, 201. Said messages include weather bulletin messages that convey local weather information and instructions, including, for example, current outside temperature information, barometric readings, and forecast data. Said messages also include meter reading messages that cause meter records of subscriber station utilities meters to be transmitted to remote metering stations.
Column 17 line 62 to column 18 line 1.	Signal processor, 200, is always operating and monitors all incoming channels. It can convey such signals to microcomputer, 205, whenever it receives them. TV signal decoder, 203, can also identify such signals but only in the one TV channel transferred by box, 201, to TV set, 202, and then only when TV set, 202, is on and operating.	Page 397 lines 17-18. ⁴⁵	Each subscriber station signal processor, 200, operates continuously; scans all incoming channels....
Column 18 lines 1-4.	Decoder, 203, transfers all received signals to processor or monitor, 204, which identifies the signals as addressed to microcomputer, 205, and transfers them to microcomputer, 205.	Page 401 lines 3-14.	Executing said forecast rain instructions causes microcomputer, 205, to cause window opening and closing means, 208, to close any open windows (and could cause the aforementioned other controlled apparatus, 260, which could be an automatic lawn watering system to cease

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
			watering). Simultaneously, by transmitting said Weather-Bulletin- 125 SPAM message to other subscriber stations of its field distribution system, 93, the station of Fig. 6 causes other subscriber stations to function in the fashion of the station of Fig. 7.
Column 18 lines 4-7.	Microcomputer, 205, uses such received signals, in a predetermined fashion, to govern the operation of furnace, 06, air conditioning system, 207, and window opening and closing means, 208.	Page 392 lines 28-30. ⁴⁶	Other controlled apparatus include electronically actuated window opening and closing means, 208, furnace, 206, air conditioning system, 207, and other controlled apparatus,....
Column 18 line 8.	Co-ordinating a Stereo Simulcast	Generally, page 406 line 33 to page 419 line 31.	<i>Length of passage precludes inclusion here.</i>
Column 18 lines 9-11.	Figure 6B illustrates a method for automatic co-ordination of a multimedia presentation in one place, in this case a stereo simulcast.	Page 406 lines 34-35.	Fig. 7B illustrates automatic control of one kind of combined medium presentation—a stereo simulcast.
Column 18 lines 11-13.	A person decides to watch a program on television that is stereo simulcast on a local radio station, too.	Page 407 lines 9-16.	At the station of Fig. 7 and 7B, a subscriber decides to watch a particular television program the audio of which is stereo simulcast on a local radio station, in a fashion well known in the art. Said subscriber switches power on to TV set, 202, and manually selects the proper channel, which is, for example, channel 13, at the television tuner, 215, of said set, 202, thereby display of the video and audio information of the transmission of said channel.
Column 18 lines 14-19.	The person turns on television, 202, and tunes to the proper channel. TV signal decoder, 203, detects signals in the programming transmission on the channel which signals it transfers to monitor or processor, 204. Monitor or processor, 204, determines that certain signals are addressed to switch, 212, and transfers these signals to switch, 212.	Page 408 lines 19-34.	Periodically thereafter, said program originating studio embeds in said transmission and transmits a particular Tune-Radio-to-FM-104.1 SPAM message that consists of a "01" header, an execution segment of particular activate-simulcast information that is addressed to URS radio decoders, 210, a meter-monitor segment that contains the "program unit identification code" information of said particular television program, appropriate padding bits, an information segment that contains particular 104.1-MHz information, and an end of file signal. Said message is detected at said decoder, 203, and inputted to said controller, 39, in the above described fashion. Receiving said message causes said controller, 39, to execute particular preprogrammed controlled function instructions that cause said controller, 39, to transfer said message to the radio decoder, 210, of radio, 209.
Column 18 lines 19-25.	These signals instruct switch, 212, to turn power on to radio, 209, and its associated equipment, including a conventional digital tuner, 213. Monitor or processor, 204, also identifies signals addressed to tuner, 213, which it transfers accordingly. These signals instruct tuner, 213, to tune radio, 209, to the proper frequency for the simulcast.	Page 410 lines 10-12.	Receiving said SPAM message causes said controller, 44, switch power on to and tune radio, 209, to the frequency, 104.1 MHz.
Column 18 lines	Automatically, by turning TV set, 202, to the channel with a stereo	Page 411 lines	Thus switching power on to TV set, 202, and selecting channel 13 at

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language

26-28.	simulcast, the person has activated the stereo simulcast.	6-9.	television tuner, 215, are the only manual steps necessary to actuate the radio simulcast of said channel at radio, 209.
Column 18 lines 29-37.	Figure 6B also shows signal processor, 200, monitoring for a data gathering and ratings service. TV signal decoder, 203, and radio signal decoder, 211, also identify certain signals that monitors or processors, 204 and 210 respectively, determine to identify the programs, etc. on the channels to which TV set, 202, and radio, 209, are tuned. The processors, 204 and 210, transfer this information to signal processor, 200, for recording and subsequent transmission to a remote data collection site.	Page 411 line 10 to page 412 line 15.	In addition, because the station of Fig. 7 (and Fig. 7B) is preprogrammed to collect monitor information, receiving said Tune-Radio-to-FM-104.1 SPAM message also causes the transmission of monitor information to the onboard controller, 14A, of said signal processor, 200, in the fashion of example #3 above. At decoder, 203, completing the controlled functions invoked by receiving said message causes the transfer, via the aforementioned bus means for communicating monitor information, to said onboard controller, 14A, of a first information transmission of the execution and meter-monitor information of said message with particular first source mark information that identifies TV set, 202. At decoder, 210, completing the controlled functions invoked by receiving said message causes the transfer, via said bus means, to said onboard controller, 14A, of a second information transmission of the execution and meter-monitor information of said message with appropriate source mark information identifying radio, 209. In the fashion of example #3 above, receiving said first transmission of monitor information causes said onboard controller, 14A, to cause a signal record of prior programming of TV set, 202, to be recorded at the recorder, 16, of signal processor, 200, (and may cause records to be transferred to a remote location) and causes said onboard controller, 14A, to initiate a first signal record, associated with source mark information that identifies TV set, 202, that is based on the "program unit identification code" information of said particular television program in the meter-monitor information of said Tune-Radio-to-FM-104.1 SPAM message. In the same fashion, receiving said second transmission of monitor information causes said onboard controller, 14A, to cause a signal record of prior programming of radio, 209, to be recorded at the recorder, 16, of signal processor, 200, (and may cause records to be transferred to a remote location) and causes said onboard controller, 14A, to initiate a second signal record, associated with source mark information that identifies radio, 209, that is based on said "program unit identification code" of said Tune-Radio-to-FM-104.1 SPAM message.
Column 18 lines 37-41.	Simultaneously, processor, 200, is also monitoring sequentially all other broadcast transmissions in the locality to gather further data on programing availability to record and transmit to a remote site.	Page 426 line 19 to page 427 line 6.	Receiving the aforementioned instance of said Select-AT&T-News-Item message and said Specific-AT&T-News-Item message at the station of Fig. 7 also causes processing of monitor information at said signal processor, 200, in the fashions described above. After transferring the information of said Select-AT&T-News-Item message to said controller, 20, said controller, 39, automatically transfers monitor information of said message to buffer/comparator, 14, thereby causing the

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
			onboard controller, 14A, to process information of the availability at said station of said AT&T news item. After executing the controlled functions invoked by said Specific-AT&T-News-Item message, said controller, 20, automatically transfers monitor information of said message to buffer/comparator, 14, thereby causing the onboard controller, 14A, to process information of the use of said AT&T news item at microcomputer, 205. And receiving said data at printer, 221, causes other decoder, 227 (see Fig. 5), in a predetermined fashion, to detect in said data the meter-monitor information of said Specific-AT&T-News-Item message and to transmit said meter-monitor information to signal processor, 200, thereby causing said onboard controller, 14A, to retain monitor information and initiate a secondary signal record in the fashion described above. <i>Length of passage precludes inclusion here.</i>
Column 18 lines 42.	Receiving Selected Information and/or Programming	Generally, page 419 line 33 to page 447 line 23.	
Column 18 lines 43-58.	Figure 6C illustrates methods for monitoring multiple programming channels and selecting programming and information in a predetermined fashion. In this example, microprocessor, 205, is programmed to hold a portfolio of stocks and to receive news about these particular stocks and about the industries they are in. Several separate news services transmit news on different channels carried on the multi-channel cable transmission to converter boxes, 222 and 201, and to signal processor, 200. The news services precede each news transmission with a unique signal that uniquely identifies the company or companies to which the news item refers and/or the industries. In a predetermined fashion, microcomputer, 205, instructs signal processor, 200, to hold examples of the sought for unique signals in its buffer/ comparator, 8, and compare them with all incoming signals.	Page 419 line 33 to page 422 line 4.	AUTOMATING U. R. STATIONS ... RECEIVING SELECTED PROGRAMMING Fig. 7C illustrates methods for monitoring multiple programming channels, selecting programming and information of interest, and receiving said selected programming and information. The microprocessor, 205, of the station of Fig. 7 and 7C, is preprogrammed to hold records of a portfolio of stocks and to receive and process automatically news items about said stocks and about the industries of said stocks. The signal processor, 200, of said station is preprogrammed at the RAM associated with the control processor, 39J, of the controller, 39, of its decoder, 30, with particular news-items-of-interest information that includes identification information of the particular stocks in said portfolio and at its controller, 20, with particular cause-selection instructions that control said controller, 20, in selecting transmissions of news items of interest. One company whose stock is preprogrammed at said microprocessor, 205, is the American Telephone and Telegraph Company whose stock is identified by particular binary information of "T". And among the news-items-of-interest information at said RAM is an instance of said binary information of "T". Two remote stations--remote news-service-A station and remote news-service-B station--transmit, from geographically separate locations, two different broadcast print transmissions. The intermediate transmission station of Fig. 6 receives and retransmits information the transmissions of said remote stations on digital data

Reference	Language	Reference	Language

Column 18 lines 58-65.	Signal processor, 200, scans sequentially all channels. When it identifies a signal of interest, it relays that information and the channel identifier, in this illustration, to microcomputer, 205. In a predetermined fashion, either microcomputer, 205, or signal processor, 200, instructs tuner, 223, to set cable converter box, 222, to the proper channel,	Page 422 line 23 to page 423 line 26.	channels A and B, respectively, that are inputted to converter boxes, 222 and 201, and to signal processor, 200. (Other intermediate stations receive and retransmit information of said transmission on other channels.) ... At the station of Fig. 7 and 7C, signal processor, 200, scans sequentially all channels at its switch, 1, mixer, 3, and decoder, 30, in the fashion of example #5. In due course, one instance of said Select-AT&T-News-Item message is detected at said decoder, 30, and inputted to the controller, 39, of said decoder, 30. Receiving said Select-AT&T-News-Item message causes said controller, 39, to transmit said message to the controller, 20, of said signal processor, 200. Automatically, controller, 39, executes particular preprogrammed controlled function instructions that cause said controller, 39, to load the binary information of "T" information of the information segment of said message at particular working register memory and determine that the information at said memory matches the aforementioned binary information of "T" that is among the news-items-of-interest information at the RAM associated with control processor, 39J. Determining a match causes said controller, 39, to transmit said message, with channel mark information that identifies the particular channel in which said message was embedded, to said controller, 20, via control information transmission means and to continue functioning in the fashion of example #5. Receiving said message causes said controller, 20, to cause a selected cable converter box, 222, to receive the transmission identified by said channel mark; to cause All signal decoder, 290, (which is identical to the TV signal decoder of Fig. 2A with the added capacity of the radio signal decoder of Fig. 2B to receive, detect, and input SPAM information embedded in radio frequency transmissions to a controller, 39, plus the added capacity of the other signal decoder of Fig. 2C to receive, detect, and input SPAM information embedded in other frequency transmissions to said controller, 39) at microcomputer, 205, to receive the transmission of a particular television frequency transmission and to commence processing detected SPAM information for an end of file signal; and to establish a programming transmission link between said selected box, 222, and All signal decoder, 290, at microcomputer, 205. In due course, said Specific-AT&T-News-Item message is transmitted on said channel A. Transmitting said message causes decoder, 290, to detect and input said message to the controller, 39, of said decoder, 290.
Column 18 line 65-67.	and microcomputer, 200, may record the information in memory or transfer it to printer, 221, for printing.	Page 425 line 15 to page 426 line 13.	

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language

			<p>Receiving said message causes said controller, 39, to cause microcomputer, 205, to process information of said message. Automatically, controller, 39, executes the instructions of a particular preprogrammed controlled function and inputs to an input buffer of microcomputer, 205, a particular input-from-290 computer job that consists of process-this-data-input-from-290 instructions and particular data. Said data includes the meter-monitor information of said message and the information of the information segment of said message--that is, said AT&T news item.</p> <p>In due course and in a predetermined fashion, microcomputer, 205, processes said job; determines that the preprogrammed instructions entered by the subscriber of the station of Fig. 7 and 7C are to print at printer, 221, data of any job of process-this-data-input-from-290 instructions; and causes said AT&T news item to be printed at said printer, 221.</p> <p>Automatically, microcomputer, 205, executes particular preprogrammed instructions and inputs a particular switch- 205-to-221 instruction to the controller, 20, of signal processor, 200. Receiving said instruction causes said controller, 20, to input particular switch control instructions to matrix switch, 258, thereby causing matrix switch, 258, to configure its switches in such a way that the input to switch, 258, from microcomputer, 205, is switched to transfer information to the output of switch, 258, that inputs to said printer, 221. Then automatically, microcomputer, 205, transfers said data to said printer, 221. In so doing, microcomputer, 205, causes printer, 221, in a predetermined fashion, to print said AT&T news item.</p>
Column 19 lines 1-2.	In the same fashion, microcomputer, 205, may also instruct signal processor, 200,	Page 267 lines 20-26.	<p>All eight of said messages are commands. The 1st- and 3rd-new-program-message (#5) and the 1st-new-radio-program- message (#5) signals are addressed to microcomputer, 205. Each informs said microcomputer of new programming transmissions to which said microcomputer can tune appropriate station receiver and display apparatus in fashions described below.</p>
Column 19 lines 2-4.	to monitor single or multiple television channels and/or radio channels for programming of interest to play or record.	Page 436 line 33 to page 437 line 3.	<p>Automatically, microcomputer, 205, compares said one instance to said program-unit-of-interest information and determines a match with said second instance. Determining a match causes microcomputer, 205, automatically to input said please-fully-enable-WSW-on-CC13-at-particular- 8:30 information to the controller, 20.</p>
Column 19 lines 5-8.	In another example, microcomputer, 205 may be preinformed that a certain television program, hypothetically "Wall Street Week," should be televised on TV set, 202, when it is cablecast.	Page 428 lines 21-26.	<p>The program-unit-of-interest information preprogrammed at the microcomputer, 205, of the station of Figs. 7 and 7C includes particular specific-WSW information that reflects the wish of the subscriber of said station to view (or record) said "Wall Street Week" program when said program is transmitted.</p>

Column 19 lines 18-20.	by passing also externally to microcomputer, 205, all signals that it passes to buffer/ comparator, 14.	Page 429 lines 8-17. ⁴⁸	identification.... The signal processor, 200, of said station scans sequentially all received television transmission channels in the fashion described above and is preprogrammed at the RAM associated with the control processor, 39J, of its decoder, 30, to respond in a particular controlled function fashion whenever a SPAM message with an execution segment of particular available-television-program information is detected. Said signal processor, 200, has capacity for actuating and tuning TV set, 202, and video recorder, 217, and for controlling microcomputer, 205.
Column 19 lines 20-23.	Analyzing these identifier signals in a predetermined fashion, microcomputer, 205, determines that "Wall Street Week" is being televised on channel X.	Page 441 lines 1-8.	Receiving said instruction and said information causes microcomputer, 205, to execute particular preprogrammed instructions and, in a predetermined fashion, to determine that the aforementioned station-specific- television-program-selection-and-display instructions at said microcomputer, 205, include particular information that the subscriber of said station is willing pay up to a certain limit--twenty-five cents--to receive said program.
Column 19 lines 23-24.	Then, in a predetermined fashion, microcomputer, 205, may instruct tuner, 214,	Page 439 lines 1-3 & 9-18. ⁴⁹	Receiving said local-cable-enabling-message (#7) at the station of Fig. 7 causes the apparatus of said station to function in precisely the fashion of example #7. ... unauthorized tampering has not occurred; to cause selected apparatus of said station--cable converter box, 201, matrix switch, 258, and a decryptor, 107 (that exists at said station, that receives its input from and transfers its output to matrix switch, 258, and is controlled by controller, 20, but that is not shown in Fig 7)--to receive the transmission of cable channel 13; to cause said selected decryptor, 107, to decrypt the audio portion of said transmission using selected cipher algorithm and key information; to cause selected apparatus of signal processor,.... ... instructions, microcomputer, 205, inputs to controller, 20, particular preprogrammed display-at-202M-and-record-at-217 instructions. Receiving said display-at-202M-and-record-at-217 instructions causes controller, 20, to switch power on to monitor, 202M, and commence transferring the television output transmission of microcomputer, 205, to said monitor, 202M; to switch power on to video recorder/player, 217, (which has capacity to receive and record the information of an audio and a composite video transmission); to commence transferring the television output transmission of microcomputer, 205, to said recorder/player, 217; and to cause said recorder/player, 217, to record said transmission.
Column 19 lines 24-29.	to switch box, 201, to channel X and may instruct control system, 220, to turn video recorder, 217, on and record "Wall Street Week," and also microcomputer, 205, may instruct switch, 216, to turn TV set, 202, on and tuner, 215, to tune appropriately to "Wall Street Week."	Page 445 lines 20-32. ⁵⁰	<i>Length of passage precludes inclusion here.</i>
Column 19 line 30.	Co-ordinating Multimedia Presentations in Time	Generally, page 447 line 25 to	

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language
Column 19 lines 31-34.	Figure 6C can also illustrate how programing delivered at different times to one place can be co-ordinated to give a multimedia presentation at one time in one place. Each weekday, microcomputer, 205, receives, about 4:30 PM, by means of a digital information channel, all closing stock prices applicable that day. It may receive these directly or it may automatically query a data service for them in a predetermined fashion. It records those prices that relate to the stocks in its stored portfolio.	page 457 line 10. Page 18 lines 24-27. ⁵¹	Fig. 7C is a block diagram of signal processing apparatus and methods selecting receivable information and programming and controlling combined medium, multi-channel presentations. Each weekday after 4:30 PM, a remote stock-price-data- transmission station transmits all closing stock price data applicable that day and causes apparatus at each subscriber station, in a predetermined fashion, to select and record at the microcomputer, 205, of said station the particular closing price datum or data that apply to the particular stock or stocks of the preprogrammed portfolio of said computer. (Said remote station transmits said closing stock price data and causes specific subscriber stations to select and process their specific information of interest in the fashion in which remote news-service-A station transmitted the AT&T news item and caused selected stations to select and process, in their specific fashions, the information of said item.) Alternatively, microcomputer, 205, is caused in a predetermined fashion (for example, by a SPAM message a given transmission monitored by signal processor, 200, in any of the above described fashions) automatically to telephone a remote data service computer, by means of network, 262, in a fashion well known in the art, and to cause said remote computer to select and transmit the particular closing price datum or data of the stock or stocks of the portfolio of said microcomputer, 205, thereby causing said microcomputer, 205, to record said datum or data in a predetermined fashion.
Column 19 lines 35-41.		Page 449 lines 13-35.	...caused his microcomputer, 205, to be preprogrammed as described above;....
Column 19 lines 42-44.	Microcomputer, 205, is preprogramed to respond in a predetermined fashion to instruction signals embedded in the "Wall Street Week" programing transmission.	Page 450 lines 31-32. ⁵²	When the "Wall Street Week" transmission begins at 8:30 PM on a Friday evening, the program instruction set in the first message of the "Wall Street Week" example instructs microcomputer, 205, to generate not one but a plurality overlays. The combining of Fig. 1C is merely the first.
Column 19 lines 45-53.	When the "Wall Street Week" transmission begins at 8:30 PM on a Friday evening, several instruction signals are identified by decoder, 203, and transferred to microcomputer, 205. These signals instruct microcomputer, 205, to generate several graphic video overlays, which microcomputer, 205, has the means to generate and transmit and TV set, 202, has the means to receive and display, and to transmit these overlays to TV set, 202, upon command.	Page 451 lines 6-11. ⁵³	Said signal is identified by decoder, 203, transferred to microcomputer, 205, and executed by microcomputer, 205, at the system level as the statement, "GRAPHICS ON". Said signal instructs microcomputer, 205, at the PC-MicroKey 1300 to overlay the graphic information in its graphics card onto the received composite video information and transmit the combined information to TV monitor, 202M. TV monitor, 202M, then
Column 19 lines 53-55.	Subsequently in the program, the host says, "Here is what the Dow Jones Industrials did is the past week,"	Page 26 lines 1-11,

Reference	Language	Reference	Language
			displays the image shown in Fig. 1C which is the microcomputer generated graphic of the subscriber's own portfolio performance overlaid on the studio generated graphic.
Column 19 lines 55-60.	and a studio generated graphic is pictured. The host then says, "Here is what the broader NASDAQ index did in the week past," and a studio generated graphic overlay is displayed on top of the first graphic. Then the host says, "And here is what your portfolio did."	& lines 20-23. Page 25 lines 26-34.	(Hereinafter, an instruction such as the above signal of "GRAPHICS ON" that causes subscriber station apparatus to execute a combining operation in synchronization is called a "combining synch command." During this time the program may show the so-called "talking head" of the host as he describes the behavior of the stock market over the course of the week. Then the host says, "Now as we turn to the graphs, here is what the Dow Jones Industrials did in the week just past," and a studio generated graphic is transmitted. Fig. 1B shows the image of said graphic as it appears on the video screen of TV monitor, 202M. Then the host says, "And here is what your portfolio did."
Column 19 lines 60-67.	At this point, an instruction signal is generated in the television studio originating the programming and is transmitted in the programming transmission. This signal is identified by decoder, 203, and transferred via processor, 204, to microcomputer, 205. This signal instructs microcomputer, 205, to transmit the first overlay to TV set, 202, for as long as it receives the same instruction signal from processor, 204.	Page 25 line 34 to page 26 line 8.	At this point, an instruction signal is generated at said program originating studio, embedded in the programming transmission, and transmitted. Said signal is identified by decoder, 203; transferred to microcomputer, 205; and executed by microcomputer, 205, at the system level as the statement, "GRAPHICS ON". Said signal instructs microcomputer, 205, at the PC-MicroKey 1300 to overlay the graphic information in its graphics card onto the received composite video information and transmit the combined information to TV monitor, 202M.
Column 19 line 68 to column 20 line 2.	The viewer then sees a microcomputer generated graphic of his own stocks' performance overlay the studio generated graphic.	Page 26 lines 8-11.	TV monitor, 202M, then displays the image shown in Fig. 1C which is the microcomputer generated graphic of the subscriber's own portfolio performance overlaid on the studio generated graphic.
Column 20 line 2-5.	When the two studio generated graphics are no longer displayed, the studio stops sending the instruction signal, and the microcomputer, 205, ceases transmitting its own graphic to TV set, 202,	Page 26 line 33 to page 27 line 7.	As the program proceeds, in the same fashion a further instruction signal is generated at said studio; transmitted; detected; inputted from decoder, 203, to microcomputer, 205; and executed as "GRAPHICS OFF." Then said studio ceases transmitting the graphic image, and transmits another image such as the host's talking head. Simultaneously, the GRAPHICS OFF command causes microcomputer, 205, to cease overlaying the graphic information onto the received composite video and to commence transmitting the received composite video transmission unmodified.
Column 20 line 5-7.	and prepares to send the next locally generated graphic overlay upon instruction from the originating studio.	Page 27 lines 7-9.	Thereafter the "Wall Street Week" program proceeds, and microcomputer, 205, continues to operate under control of received instructions.
Column 20 line 8-10.	This is only one of many examples of the co-ordination at one time and in one place of programming and information material delivered at different times.	Page 27 line 34 to page 28 line 3.	This "Wall Street Week" portfolio performance example provides but one of many examples of television based combined medium programming. This television based combined medium is but one example of many

Column 20 line 11.	Co-ordinating Print and Video		combined media. <i>Length of passage precludes inclusion here.</i>
Column 20 lines 12-15.	Figure 6D illustrates one method for co-ordinating the presentation of information through the use of print with video. Figure 6D also illustrates possible uses of a decrypter and a local input.	Page 469 lines 3-6. ⁵⁵	Fig. 7F illustrates a method for generating and communicating information to selected subscribers through the coordination of computers, television, and broadcast print. Fig. 7F also illustrates use of a local input, 225.
Column 20 lines 16-23.	Suppose a viewer watches a television program on cooking techniques that is received on TV set, 202, via box, 201. Julia Childs's "The French Chef" is one such program. Halfway through the program, the host says, "If you are interested in cooking what we are preparing here and want a printed copy of the recipe for a charge of only 10 cents, press 567 on your Widget Signal Generator and Local Input."	Page 469 lines 7-8. ⁵⁶	The microcomputer, 205, of the station of Fig. 7 and 7F, is preprogrammed to receive and process automatically....
Column 20 lines 23-27.	The viewer then presses buttons 567 on local input, 225, which signal is conveyed to the buffer/comparator, 8 (referring to Fig. 1), of signal processor, 200, to hold and process further in a predetermined fashion.	Page 471 lines 14-21.	Each subscriber—in particular, the subscriber of the station of Figs. 7 and 7F, said second subscriber, and said third subscriber—enters TV 567#, in a fashion well known in the art, at the keyboard of the specific local input, 225, of his own station which causes said input, 225, to transmit a particular preprogrammed process-local-input instruction and said TV 567# information to the controller, 20, of the signal processor, 200, of said station.
Column 20 lines 27-30.	Five minutes later, a signal is identified in the incoming programming on TV set, 202, by decoder, 203, which is also transferred by processor, 204, to buffer/comparator, 8, of signal processor, 200.	Page 471 line 26 to page 472 line 4.	Five minutes later, said program originating studio embeds in the transmission of the "Exotic Meals of India" programming and transmits a particular first SPAM message that consists of an "01" header, particular execution segment information that is addressed to URS signal processors, 200, appropriate meter-monitor information, padding bits as required, an information segment of particular check-for-entered-information-and-process instructions, and an end of file signal. At the station of Figs. 7 and 7F, said message is detected at TV signal decoder, 145, and said execution segment information invokes particular controlled function instructions that cause said message to be transferred to the controller, 20, of signal processor, 200.
Column 20 lines 31-33.	This signal instructs buffer/comparator, 8, that, if 567 has been received from signal generator, 225, signal processor, 200,	Page 472 lines 13-23.	Receiving said message causes controller, 20, to load and execute said check-for-entered-information-and-process instructions, and executing said instructions causes controller, 20, to determine that TV 567# information exists at said last-local-input-# memory and to cause an instance of particular covert control information (which is preprogrammed in said instructions) to be placed at particular control- function-invoking information memory of the controller, 39, of decoder, 145, and also at

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language

			particular control-function- invoking information memory of the controller, 39, of decoder, 203.
Column 20 lines 33-37.	should, in a predetermined fashion, instruct tuner, 223, to tune cable converter box, 222, to the appropriate channel to receive the recipe in encoded digital form and instruct control means, 226, to activate printer, 221.	Page 477 lines 8-23.	In this alternate method, executing said check-for-entered-information-and-process instructions of said first SPAM message causes controller, 20, of signal processor, 200, of each one of said stations to cause the tuner, 223, of a selected converter box, 222, to tune said box, 222, to receive said second transmission; to cause the matrix switch, 258, to establish a programming communication link between said selected converter box, 222, and said decoder, 290; to cause the appropriate receiver apparatus of said decoder, 290, to receive said transmission and the appropriate detector and EOFs valve, 39F, to commence detecting an end of file signal; and to cause an instance of particular covert control information that is in said instruction to be placed at particular control-function- invoking information memory of the controller, 39, of said decoder, 290.
Column 20 lines 37-42.	The signal transmission from processor, 204, also passes a signal word to signal processor, 200, which, in a predetermined fashion, signal processor, 200, decrypts and transfers to decrypter, 224, to serve as the code upon which decrypter, 224, will decrypt the incoming encrypted recipe.	Page 478 lines 1-5.	(Whichever transmission method is employed the information of said second message can be encrypted and caused to be decrypted in any of the methods described above—for example, in the method of the first message of example #4.)
Column 20 lines 42-46.	Then, as part of the predetermined operation, signal processor, 200, conveys to its data recorder, 16, information that the 567 order was placed by the viewer and all necessary equipment was enabled.	Page 472 lines 23-27.	Executing said instructions also causes controller, 20, to initiate a particular signal record of meter information at the buffer, 14, of signal processor, 200, which record contains particular program unit information and TV567# information.
Column 20 lines 46-48.	When the transmission of the recipe is received, box 222, transfers the transmission to decrypter, 224, for decryption	Page 473 lines 14-18	At the station of Figs. 7 and 7F, said message is detected at TV signal decoder, 145, and said execution segment information invokes particular controlled function instructions that cause said message to be transferred to the controller, 39, of decoder, 203.
Column 20 lines 48-49.	and thence to printer, 221, for printing.	& lines 29-31.	Receiving said message causes the controller, 39, of decoder, 203, to load and execute said generate-recipe-and- shopping-list instructions at microcomputer, 205,
Column 20 lines 49-54.	Other signal decoder, 227, identifies a signal in the transmission received by printer, 221, which it passes via processor, 228, and buffer/comparator, 14, of signal processor, 200, to data recorder, 16. This signal indicates that the recipe, itself, has been received.	Page 475 lines 1-2. Page 473 line 31 to page 474 line 1.	Receiving said output information causes printer, 221, to print the information of said specific recipe and list. ...shopping-list instructions at microcomputer, 205, and to transfer particular meter-monitor information to the buffer/comparator, 14, of signal processor, 200, causing said buffer/comparator, 14, to increment the information of said signal record of meter information in the fashion described above.
Column 20 lines	Subsequently, when signal processor, 200, transfers the data in its data	Page 510 lines	... causes controller, 20, in the fashion described above, to cause auto

54-58.	recorder, 16, via telephone to a remote site, that site can determine for billing purposes that the recipe was, first, ordered and, second, delivered.	28-32. ³⁷	dialer, 24, to dial the telephone number, 1-(800) 247-8700. Automatically, in the fashion described above, controller, 20, establishes telephone communications with a computer of said super market....
Column 20 lines 59-62.	(An alternate method for transmitting the recipe to printer, 221, would be for the recipe, itself, to be located in encoded digital form in the programing transmission recieved by TV set, 202.	Page 476 line 34 to page 477 line 3. ³⁸	(An alternate method for inputting said second message to the microcomputers, 205, at stations where TV567# is entered at a local input, 225, is to embed said message in a particular second transmission that is different from the transmission....
Column 20 lines 62-63.	In this case, decoder, 203, would identify the signals conveying the recipe	Page 473 lines 14-18.	At the station of Figs. 7 and 7F, said message is detected at TV signal decoder, 145, and said execution segment information invokes particular controlled function instructions that cause said message to be transferred to the controller, 39, of decoder, 203.
Column 20 lines 63-65.	and transfer them via processor, 204, to signal processor, 200, which would decrypt them, itself,	Page 478 lines 1-5.	(Whichever transmission method is employed the information of said second message can be encrypted and caused to be decrypted in any of the methods described above--for example, in the method of the first message of example #4.)
Column 20 lines 65-67.	and transfer them, via means which in this case it would have, to printer, 221).	Page 475 lines 1-2.	Receiving said output information causes printer, 221, to print the information of said specific recipe and list.
Column 21 lines 1-2.	Using <u>Signaling and Decryption Techniques to Control Distribution of Copyrighted Materials</u>	Generally, page 312 lines 12-28. ³⁹	And for example, the transmitted programming may be only audio (for example, of a radio transmission) or print (for example, of broadcast print) rather than television. And for example, the output apparatus may be speakers or one or more printers rather than a television monitor. And for example, rather than being a transmitter at a remote wireless or cable transmission station, the source of the transmission may be a local apparatus such as a video (or audio or digital information) tape recorder or a laser disc player, well known in the art, that transmits a transmission of conventional rerecorded programming that has been encrypted (either fully or partially) and in which SPAM regulating instructions and information have been appropriately prerecorded which transmission is inputted to matrix switch, 258, from said local apparatus and which SPAM regulating instructions cause the decryption of the encrypted programming in the fashions of the present invention.
Column 21 lines 3-8.	Figure 6E illustrates a signaling and decryption technique which could serve to facilitate the electronic distribution of copyrighted materials such as books and movies by tending to discourage piracy and the unauthorized retransmission of copies, whether they be properly acquired or pirated.	Page 306 line 20 to page 307 line 1.	(By causing information that identifies the station at which encrypted information is decrypted to be so inserted, the present invention makes it possible to identify particular stations where their information is misused--for example, if pirated decrypted copies of information are distributed, the station at which decryption occurred can be identified by means of the inserted information--and by causing said information to be inserted and then processed at a decryptor as if said inserted information were encrypted, the present invention renders the inserted information into a form that can easily be rendered back into clear form--for example, by

51-53.	this second signal word or words.	34 to page 306 line 4.	information, in a fashion well known in the art, from a particular strip-designated portion of the video transmission received at said stripper, 229, and transfer the received video, without said stripped information, to matrix switch, 258.
Column 21 lines 53-63.	Signal processor, 200, also passes the customer's name and address and its own unique apparatus identifier code from read only memory, 21, to signal generator, 230, which generates a signal embedding the customer's name and address and the retail outlet's identification in the programming in a suitable place or places in a suitable fashion. (Signal processor, 200, may also transmit the customer's name and address to printer or other means, 221, for actual printing of the customer's name and address in the text.)	Page 306 lines 11-19.	Automatically, controller, 20, selects complete information of the aforementioned unique digital code at ROM, 21, transmits said complete information to signal generator, 230, and causes said generator, 230, to insert said complete information, in a predetermined periodic fashion and in an inserting fashion well known in the art, into a particular insertion-designated portion of the video transmission received at said generator, 230, and to transfer the received video, with said inserted information, to matrix switch, 258.
Column 21 lines 63-65.	The transmission then passes through decryptor, 231, which completes the decryption process	Page 305 lines 29-31;	...to commence transferring the information inputted from signal generator, 230, to the output that outputs to decryptor, 231,...
Column 21 lines 65-66.	and passes the decrypted programming transmission to printer or other means, 221,	and lines 14-16.	...and to affect a second and last stage of decrypting the digital video information of the "Wall Street Week" program transmission.
Column 21 lines 66-67.	and also to signal processor, 200.	Page 309 line 27 to page 310 line 3. ⁶⁴	Determining that signal stripper, 229, and that signal generator, 230, are stripping and inserting correctly (after having determined that that decryptors, 224 and 231, are decrypting correctly) causes the controller, 20, of the station of Fig. 4 (and causes controllers, 20, at other stations where so determining occurs) to execute particular additional 2nd-stage-enable-WSW-program instructions, and executing said instructions causes controller, 20, to cause the apparatus of the station of Fig. 4 to commence transferring the decrypted television information of the "Wall Street Week" program to microcomputer, 205, and monitor, 202M.
Column 21 line 67 to column 22 line 2.	Signal processor, 200, receives and analyzes the signal content of the programming output of decrypter, 231 to ensure that stripper, 229, and generator, 230, have functioned properly.	Page 305 lines 31-34.	...and to commence transferring the information inputted from decryptor, 231, to the output that outputs to said third alternate contact of switch, 1.
		Page 308 lines 13-30.	Receiving said signal causes controller, 20, under control of said 2nd-stage-enable-WSW-program instructions, to cause said control processor, 391, to transfer to controller, 20, selected information of said check sequence; to compare said selected information to selected information of said 2nd-stage-enable-WSW-program instructions; and to determine that a match results, indicating that decryptors, 224 and 231, are decrypting received information correctly. Determining a match causes controller, 20, to determine, in a predetermined fashion, that signal stripper, 229, is correctly stripping information from the aforementioned strip-designated portion of the video transmission and transferring received

Column 22 lines 2-4.	If they have not, signal processor, 200, shuts down the decryption of the title and prevents its delivery to the customer.	Page 308 line 31 to page 309 line 11.	video without said stripped information and that signal generator, 230, is correctly inserting complete information of the aforementioned unique digital code into the aforementioned insertion-designated portion of the video transmission and transferring received video with said inserted information. (Simultaneously other stations compare selected information of said check sequence to selected information of said 2nd-stage-enable-WSW-program instructions and verify the correct functioning of local signal strippers, 229, and generators, 230. At each station where a controller, 20, determines that a match does not result—which indicates that a decryptor, 224 or 231, is not decrypting its received information correctly and suggests that the preprogrammed SPAM operating information of said station may have been tampered with—or determines that a stripper, 229, or a generator, 230, fails to function correctly, so determining match causes said controller, 20, to cause all information of said 2nd-WSW-program-enabling-message (#7) to be erased from all memory of said station except for a particular portion of said 2nd-stage-enable-WSW-program instructions loaded at the RAM of said controller, 20,....
Column 22 lines 5-15.	The General Case It is obvious to one of ordinary skill in the art that the foregoing is presented by way of example only and that the invention is not to be unduly restricted thereby since modifications may be made in the structure of the various parts without functionally departing from the spirit of the invention. Figure 6 should make this clear. The receiver site depicted in Figure 6 has multiple means for receiving programming transmissions. All received programming is analyzed and evaluated by signal processor, 200.	Page 556 line 33 to page 557 line 32.	It is obvious to one of ordinary skill in the art that the foregoing is presented by way of example only and that the invention is not to be unduly restricted thereby since modifications may be made in the structure of the various parts or in the methods of their functioning without functionally departing from the spirit of the invention. Any SPAM message and any other programming transmission can be caused, through encryption/decryption and other SPAM regulating techniques of the present invention, to take affect fully only selected stations and station apparatus. Because any transmission station can invoke any SPAM controlled function by transmitting a SPAM message with meter-monitor segment information, invoking any given SPAM controlled function can also cause meter information and or monitor information to be processed in the fashions described above at apparatus and stations where said controlled function is invoked. Intermediate transmission stations can be equipped with SPAM regulating capacity such as that illustrated in Fig. 4, monitoring capacity such as that illustrated in Fig. 5, and control information switching and bus communications capacity such as that illustrated in Figs. 7 and 8. Controlling such capacity by means of transmitted SPAM messages, a remote network origination and control station can transmit programming to intermediate transmission stations, regulate and meter the use of said programming at said stations, monitor the use and usage of said programming at said stations, and control

Reference	Language	Reference	Language
Column 22 lines 15-20.	Working with microcomputer, 205, which is preprogrammed to present received programming in predetermined fashions determined at the receiver site, signal processor, 200, permits and facilitates such presentations in accordance with the intentions of the suppliers of the programming at remote sites.	Page 428 line 21 to page 429 line 17.	<p>communication of control information at said stations all in the fashions that apply above to ultimate receiver stations. And any given transmission station can cause its receiver stations to function automatically not only in the fashions described above in the sections on automating ultimate receiver stations but in any appropriate fashion that a network origination and control station can cause intermediate transmission stations to function automatically.</p> <p>The program-unit-of-interest information preprogrammed at the microcomputer, 205, of the station of Figs. 7 and 7C includes particular specific-WSW information that reflects the wish of the subscriber of said station to view (or record) said "Wall Street Week" program when said program is transmitted. In a predetermined fashion, said subscriber has caused to be included in said program-unit-of-interest information. (Microcomputers, 205, of selected other stations of said large plurality of stations are also so preprogrammed.) The station-specific-television-program- selection-and-display instructions at the microcomputer, 205, of the station of Figs. 7 and 7C includes particular information that said subscriber will pay up to a certain limit—for example, twenty-five cents—to be permitted to receive said program and that, if the TV set, 202, of said station is switched off when information of the transmission of said program is detected, power should be switched on to said TV set, 202, and said program should be displayed at the monitor, 202M, of said set and, in addition, power should be switched on to the video recorder/player, 217, of said station, and said program should be recorded at said recorder/player, 217.</p> <p>The signal processor, 200, of said station scans sequentially all received television transmission channels in the fashion described above and is preprogrammed at the RAM associated with the control processor, 39J, of its decoder, 30, to respond in a particular controlled function fashion whenever a SPAM message with an execution segment of particular available-television-program information is detected. Said signal processor, 200, has capacity for actuating and tuning TV set, 202, and video recorder, 217, and for controlling microcomputer, 205.</p> <p>Automatically, controller, 20, transmits particular information to said decoder, 145, that causes said decoder, 145, to determine, in a predetermined fashion, that power is not on to monitor, 202M, and to respond by transmitting particular 202M-is-not-on information to controller, 20, via said link.</p> <p>The fact that monitor, 202M, is not on signifies that the subscriber of the station of Fig. 7 is not viewing television information at monitor, 202M, and suggests that said subscriber may not even be present at said station.</p>
Column 22 lines 20-24.	Working together, signal processor, 200, and microcomputer, 205, can control all local equipment and manage local presentations in any fashion feasible given the nature of the local equipment and the programming.	Page 444 line 31 to page 445 line 22.	

1981 Specification, referenced to Applicants' U.S. Pat. No. 4,690,490		1987 Instant Specification	
Reference	Language	Reference	Language

			<p>Receiving said 202M-is-not-on information causes controller, 20, under control of said additional 2nd-stage- enable- WSW- program instructions, to cause microcomputer, 205, to input particular preprogrammed instructions to said controller, 20, which instructions reflect the specific fashion in which said subscribe wants any given selected program to be selected and displayed. Automatically, controller, 20, inputs a particular choose-mode-of-selection- and-display instruction and said 202M-is-not-on information to microcomputer, 205, and receiving said instruction and said information causes microcomputer, 205, in a predetermined fashion, to process the aforementioned station-specific-television-program-selection-and-display instructions. Automatically, under control of said instructions, microcomputer, 205, inputs to controller, 20, particular preprogrammed display-at-202M-and-record-at-217 instructions.</p>

GLOSSARY OF DEFINED TERMS

1987 Priority U.S. Patent Application

The following terms are defined and used in specific ways in U.S. Patent No. 4,965,825 and its continuations, including Applicants' instant specification. Terms that appear at the left margin in quotation marks are formally defined in the patent disclosures. The meanings of terms that are shown below without quotation marks are made clear in the context in which they appear.

A

B

"broadcast" ... page 12 line 22 ... to transmit programming over-the-air.

"broadcast print" ... page 1 line 25 ... Radio and electronic print services such as stock brokers' so-called "tickers" and "broad tapes" are ... powerful, user friendly mass media. (Hereinafter, the electronic print mass medium is called, "broadcast print.")

C

cadence information ... page 60 line 12 ... Cadence information which consists of headers, certain length tokens, and signals that are called "end of file signals" enables subscriber station apparatus to distinguish each instance of header information in any given message stream and, hence, to distinguish the individual messages of said stream. In the present invention, subscriber station apparatus are preprogrammed to process cadence information.

"cablecast" ... page 12 line 23 ... to transmit programming over hard-wire.

"combined" media ... page 2 line 17 ... Today great potential exists for combining the capacity of broadcast communications media to convey ideas with the capacity of computers to process and output user specific information. One such combination would provide a new radio-based or broadcast print medium with the capacity for conveying general information to large audiences--e.g., "Stock prices rose today in heavy trading,"--with information of specific relevance to each particular user in the audience--e.g., "but the value of your stock portfolio went down." (Hereinafter, the new media that result from such combinations are called "combined" media.)

"combining synch command" ... page 26 line 20 ... (Hereinafter, an instruction such as the above

signal of "GRAPHICS ON" that causes subscriber station apparatus to execute a combining operation in synchronization is called a "combining synch command." Said initial signal word or words that preceded the above program instruction set provide another example of a combining synch command in that said word or words synchronized all subscriber station computers in commencing loading and running information for a particular combining.)

command ... page 44 line 12 ... As Fig. 2E shows, [a] header and execution and meter-monitor segments constitute [one form of] a command.

A command is an instance of signal information that is addressed to particular subscriber station apparatus and that causes said apparatus to perform a particular function or functions.

A command is always constituted of at least a header and an execution segment. With respect to any given command, its execution segment contains information that specifies the apparatus that said command addresses and specifies a particular function or functions that said command causes said apparatus to perform. (Hereinafter, functions that execution segment information causes subscriber station apparatus to perform are called "controlled functions.")

Commands often contain meter-monitor segments. ...

...

... page 47 line 11 ... Commands can address many apparatus and execute many controlled functions.

"control invoking instructions" ... page 23 line 24 ... see "invoking broadcast control"

"controlled functions" ... page 44 line 22 ... (Hereinafter, functions that execution segment information causes subscriber station apparatus to perform are called "controlled functions.")

...

... page 46 line 8 ... Examples of controlled functions include:

Load and run the contents of the information segment.

Decrypt the execution segment using decryption key G.

Decrypt the execution and meter-monitor segments using decryption key J.

Commence the video overlay combining designated in the meter-monitor segment.

Modify the execution segment to instruct URS microcomputer, 205, to commence overlay designated in meter-monitor segment, record the contents of the execution and meter-monitor segments, and transfer command to URS microcomputer, 205.

Print the contents of the information segment.

Record the contents of the execution and meter-monitor segments; transfer them to URS decryptors, 224, and execute the preprogrammed instructions that cause URS decryptors, 224, to commence decrypting with said contents as decryption key; execute preprogrammed instructions that cause URS cable converter boxes, 222, to switch to cable channel Z; execute preprogrammed instructions that cause URS matrix switches, 258, to configure its switches to transfer the input from converter boxes, 222, to decryptors, 224, and the output from decryptors, 224, to microcomputers, 205; modify the execution segment to instruct URS microcomputers, 205, to commence loading and executing the information received from URS decryptors, 224 via URS switches, 258.

"controller, 39" ... page 156 line 26 ... More precisely, controller, 39, of decoder, 203, and SPAM-controller, 205C, are one and the same (and are called, hereinafter, "controller, 39"). Thus the preferred embodiment of controller, 39, is configured and preprogrammed not only to control the detecting, correcting, converting, and executing of controlled functions at decoder, 203, but also to input to and execute at microcomputer, 205, the information of any given detected SPAM message that is addressed to URS microcomputers, 205.

"covert control" ... page 218 line 6 ... By themselves, the first and second features provide a technique whereby a message such as the second message of the "Wall Street Week" program can take affect at only selected stations (such as those stations preprogrammed with decryption key J) without being decrypted at said stations. (Hereinafter, this technique is called "covert control.")

"covert control-invoking value" ... page 285 line 7 ... (Hereinafter, the normal binary value of a given instance of information that invokes a preprogrammed function--such as, for example, the "100110" that is the normal value of said execute-conditional-overlay-at-205 information--is called a "standard control-invoking value", and a value that temporary replaces a standard control-invoking value in the course a covert control application-- such as "111111" in example #6--is called a "covert control-invoking value".)

"CPU" ... page 22 line 33 ... central processor unit ... also defined at page 87 line 21 as ... central processor unit

D

- "data module set" ... page 365 line 24 ... (Hereinafter, a data module that is transmitted to subscriber stations and processed by computers of said stations under control of instructions of a program instruction set is called a "data module set,"
- "data module set of Q" ... page 366 line 18 ... (Hereinafter, the data module set generated in example #9, under control of said intermediate generation set of Q, is called the "data module set of Q".)
- "data module set of Q.1" ... page 378 line 31 ... (Hereinafter, the data module set generated at the station of Fig. 6 in example #10 is called the "data module set of Q.1", signifying that said set is one version of complete data module set information of said instance of the network transmission of Q.)
- "data module set of Q.2" ... page 380 line 33 ... [Hereinafter, the data module set generated at said second station is called the "data module set of Q.2", signifying that said set is a second version of complete data module set information of said instance of the network transmission of Q.)]

E

end of file signals ... page 62 line 26 ... distinctive end of file signals are required to communicate the locations of the ends of information segments to subscriber station apparatus. In the present invention, each end of file signal is transmitted immediately after the end of an information segment; said signal is part of the information of the message in which said segment occurs; and said signal is located at the end of said message.

At any given time, subscriber station apparatus are preprogrammed to process only one distinct signal as an end of file signal. In order for said apparatus to distinguish an instance of said signal from all other signal information, an end of file signal must differ distinctly from all other information. Signal information, especially information transmitted in an information segment, can vary greatly in composition. Accordingly, to be distinctive, an end of file signal must be long and complex to detect.

An end of file signal consists of a particular sequence of bits of binary information. In the preferred embodiment each bit is identical to every other bit; that is, disregarding error correction information, an end of file signal consists of a sequence of "1" bits (eg. "11111111") or "0" bits (eg. "00000000"). In the preferred embodiment, end of file signals are composed of "1" bits rather than "0" bits.

see EOFs, EOFs bit and MOVE bit

EOFs ... refers to End Of File Signal ... see end of file signals

"EOFs bit" ... page 64 line 1 ... An end of file signal consists of a particular sequence of bits of binary information. In the preferred embodiment each bit is identical to every other bit; that is, disregarding error correction information, an end of file signal consists of a sequence of "1" bits (eg. "11111111") or "0" bits (eg. "00000000"). In the preferred embodiment, end of

file signals are composed of "1" bits rather than "0" bits. Zero is a value that occurs frequently in data and in mathematics, and however many bits may occur in a binary data word that consists of a series of "0" bits, the numeric value of said word remains zero. Numeric values that are represented in binary form by a sequence of "1" bits, especially a sequence that is long, occur in data and mathematics far less frequently than zero. Thus the preferred composition bit is "1" because the chance of data being joined in a given signal in such a way that two or more instance of information combine inadvertently and create the appearance of an end of file signal is far smaller if the preferred bit is "1" than if it is "0". (Hereinafter, the preferred binary end of file signal composition bit, "1", is called an "EOFS bit," and for reasons that are explained below, the alternate binary bit, "0", is called a "MOVE bit.")

"EOFS Complete Flag" ... page 69 line 10 ... see EOFS valve components

"EOFS Empty Flag" ... page 69 line 10 ... see EOFS valve components

"EOFS Standard Length Location" ... page 69 line 10 ... see EOFS valve components

"EOFS Standard Word Location" ... page 69 line 10 ... see EOFS valve components

"EOFS valve" ... page 65 line 19 ... an apparatus, called an "EOFS valve," that detects end of file signals

EOFS valve components ... page 69 line 10 ... In the present invention, any microprocessor, buffer/comparator, or buffer can be adapted and preprogrammed to detect end of file signals. At any given SPAM apparatus that is so adapted and preprogrammed, particular dedicated capacity exists for said detecting. Said capacity includes standard register memory or RAM capacity, well known in the art, including three particular memory locations for comparison purposes, one particular memory location to serve as a counter, and three so-called "flag bit" locations to hold particular true/false information. (Hereinafter, said three particular memory locations, said one particular memory location, and said three flag bit locations are called the "EOFS Word Evaluation Location," "EOFS Standard Word Location," and "EOFS Standard Length Location"; the "EOFS WORD Counter"; and the "EOFS WORD Flag," "EOFS Empty Flag," and "EOFS Complete Flag" all respectively.)

"EOFS WORD" ... page 70 line 12 ... (Hereinafter, one signal word of EOFS bits is called an "EOFS WORD.")

"EOFS WORD Counter" ... page 69 line 10 ... see EOFS valve components

"EOFS Word Evaluation Location" ... page 69 line 10 ... see EOFS valve components

"EOFS WORD Flag" ... page 69 line 10 ... see EOFS valve components

"EPROM" ... page 33 line 17 ... erasable programmable ROM [or other forms of programmable nonvolatile memory]

execution segment ... page 45 line 22 ... Execution segment information includes the subscriber station apparatus that the command of said segment addresses and the controlled functions said apparatus is to perform. ("ITS" refers, hereinafter, to intermediate transmission station apparatus, and "URS" refers to ultimate receiver station apparatus.) [Some] examples of addressed apparatus include:

ITS signal processors (in 71 in Fig. 6),
ITS controller/computers (73 in Fig. 6),
URS signal processors (200 in Fig. 7),
URS microcomputers (205 in Fig. 7),
URS printers (221 in Fig. 7), and
URS utilities meters (262 in Fig. 7).

... page 47 line 16 ... Execution segment information operates by invoking preprogrammed operating instructions that exist at each subscriber station apparatus that is addressed. ... [see controlled function]

For each appropriate addressed apparatus and controlled function combination a unique execution segment binary information value is assigned. ...

For any given command, the execution segment information of said command invokes, at each relevant subscriber station apparatus, the preprogrammed operating instructions uniquely associated with its particular binary value in particular comparing and matching fashions that are described [extensively.]

The determination of appropriate addressed apparatus and controlled function combinations takes into account the facts that different apparatus, at any given subscriber station, can be preprogrammed to interpret any given instance of execution segment information differently and that subscriber station apparatus can be preprogrammed to automatically alter execution segment information. ...

...

... page 49 line 16 ... In the preferred embodiment, at any given time the number of binary information bits in any given instance of execution segment information is a particular constant number. [see "X."]

F

"field" ... page 50 line 28 ... see "meter-monitor field."

first combining synch command ... page 89 line 8 ... Each example focuses on the processing of the three signal messages of the Fig. 1C combining. The information of said messages include three combining synch commands and one program instruction set.

The first message is of the information associated with the first combining synch command. [See page 23 line 35 through page 24 line 16 of the specification as well as "combining synch command" above.] Said first command has a "01" header, an execution segment, and a meter-monitor segment of six fields. Said command is followed by an information segment that contains said program instruction set, and said information segment is followed by an end of file signal. Said first command addresses URS microcomputers, 205, and causes said computers, 205, to load and run the program instruction set transmitted in the information segment. Each meter-monitor segment field of said command contains information that identifies one of the following:

- . the origin of said "Wall Street Week" transmission,
- . the subject matter of said "Wall Street Week" program,
- . the program unit of said program,
- . the day of said transmission within a particular one hundred year period,
- . the supplier of the program instruction set in the information segment following said first combining synch command, and
- . the format of said meter-monitor segment information.

G

"guide commands ... page 267 line 26 ... All eight of said messages are commands. The 1st- and 3rd-new-program-message (#5) and the 1st-new-radio-program- message (#5) signals are addressed to microcomputer, 205. Each informs said microcomputer of new programming transmissions to which said microcomputer can tune appropriate station receiver and display apparatus in fashions described below. (Hereinafter said commands are called "guide commands" because they can guide station control apparatus to desired programming.) By contrast, the 1st-, 2nd-, and 3rd-old-program-message (#5) messages, the 2nd-new-program-message (#5), and the 1st-old-radio-program- message (#5) inform no station control apparatus of new programming transmissions because said commands are addressed to no apparatus; the execution segment of each is the aforementioned

pseudo-command. (Hereinafter, each said signal is called a "transparent command" because no subscriber station control apparatus "sees" said signal.)

H

"H" ... page 95 line 30 ... a particular preprogrammed constant number of the first converted bits of said binary information. Said constant number is the number of bits in a SPAM command header. (Hereinafter, said constant number is called "H".)

"H+X" ... page 127 line 13 ... At any given time, any given instance of "10" header message command information is of one constant binary length--the aforementioned header+exec constant length. (Hereinafter, said length is called "H+X" and is the sum of H plus X.)

"H+X+L" ... page 110 line 16 ... a particular preprogrammed constant number that is the sum of H plus X plus L to the x-bits information at said SPAM-length-info memory. (Hereinafter, said constant is called "H+X+L".)

header ... page 45 line 4 ... In simple preferred embodiments, at any given time the number of binary information bits in any given instance of header information is a particular constant number. In other words, every header contains the same number of bits. In the simplest preferred embodiment, said constant number is two, all headers consist of two bits binary information, and commands are identified by one of three binary headers:

10 - a command with an execution segment alone;

00 - a command with execution and meter-monitor segments; and

01 - a command with execution and meter-monitor segments that is followed by an information segment.

... page 54 line 12 ... In the simplest preferred embodiment, a fourth type of header is:

11 - an additional information segment transmission following a "01" header command and one or more information segments which additional segment is addressed to the same apparatus and invokes the same controlled functions as said "01" command.

I

information segment ... page 53 line 33 ... Information segments follow commands and can be

of any length. Program instruction sets, intermediate generation sets, other computer program information, and data (all of which are organized in a fashion or fashions well known in the art) are transmitted in information segments. An information segment can transmit any information that a processor can process. It can transmit compiled machine language code or assembly language code or higher level language programs, all of which are well known in the art. Commands can execute such program information and cause compiling prior to execution.

"intermediate generation sets" ... page 42 line 8 ... (Hereinafter, instances of computer program information that cause intermediate transmission station apparatus to generate program instruction set information and/or command information are called "intermediate generation sets.") ... see also "program instruction set" ... "intermediate generation set" is also defined at page 356 line 13 as ... (Hereinafter, an instance of computer program instructions that cause a computer, at an intermediate transmission station, to generate information of a program instruction set is called an "intermediate generation set.")

"intermediate generation set of Q" ... page 359 line 9 ... (Hereinafter, the intermediate generation set that causes any given intermediate transmission station to generate a program instruction set of an instance of the transmission of the programming of program unit Q is called the "intermediate generation set of Q".)

"intermediate transmission stations" ... page 40 line 33 ... (Hereinafter, ... stations that receive and retransmit broadcast transmissions are called "intermediate transmission stations", ...

"interval," as in "interval Q" of unit Q ... page 355 line 26 ... When the aforementioned remote distribution station inputs information to computer, 73, via network, 98, regarding unit Q, said distribution station inputs information that Q is particular combined medium programming and instructs computer, 73, to commence particular program instruction set generation in a particular fashion at a particular time interval prior to the scheduled playing of Q. (Hereinafter, a particular instance of such a time period is called "interval," as in "interval Q" of unit Q.)

"invoking broadcast control" ... page 23 line 25 ... Operating in said preprogrammed fashion under control of said first set of instructions, microcomputer, 205, reaches a stage at which the subscriber can input information only under control of signals embedded in the broadcast transmission and can reassume control of microcomputer, 205, ... only by executing a system reset (or so-called "warm boot") which on an IBM PC is accomplished by ... (Hereinafter, this first set of instructions is called the "control invoking instructions," and the associated steps are called "invoking broadcast control".)

"ITS" ... page 45 line 25 ... refers to intermediate transmission station apparatus.

J

K

L

"L" ... page 103 line 4 ... a third preprogrammed constant number of next bits and record said bits at particular memory. Said third constant number is the particular number of bits in an instance of SPAM meter-monitor format field length token information. (Hereinafter, said third constant number is called "L".)

"length token" ... page 52 line 5 ... each instance of a meter-monitor segment includes a format field that contains information that specifies the particular format of the meter-monitor segment of said instance. Within said field is a particular group of binary information bits (hereinafter, the "length token") that identifies the number of bits in a meter-monitor segment of said format. Each alternate length token has a unique binary information code. The number of information bits in each instance of a length token is the smallest number of bits capable of representing the binary value of the total number of meter-monitor segment bit length alternatives. And the unique code of each different alternative is within the range of binary numbers thus defined.

...

... page 53 line 20 ... In the preferred embodiment, the bits of the length token are the first bits in each meter-monitor segment. ...

M

"message" ... page 59 line 24 ... All of the information transmitted with a given header is called a "message." Each header begins a message, and each message begins with a header. More specifically, a message consists of all the SPAM information, transmitted in a given transmission, from the first bit of one header to the last bit transmitted before the first bit of the next header.

A SPAM message is the modality whereby the original transmission station that originates said message controls specific addressed apparatus at subscriber stations. The information of any given SPAM transmission consists of a series or stream of sequentially transmitted SPAM messages.

"meter command" ... page 48 line 33 ... The preferred embodiment includes ... one command that is addressed to URS signal processors, 200, (hereinafter, the "meter command") but does not instruct said processors, 200, to perform any controlled function. [This command is] always transmitted with meter-monitor segment data that receiver station apparatus automatically

process and record. By transmitting ... meter command signals, transmission stations cause receiver station apparatus to record meter-monitor segment information without executing controlled functions. ... The meter command causes apparatus such as controller, 12, of Fig. 2D to transmit meter information to buffer/comparator, 14, without performing any controlled function.

"meter-monitor field" ... page 50 line 28 ... For each category of [meter information and/or monitor] information, a series of binary bits (hereinafter, a "field" or "meter-monitor field") exists in the meter-monitor segment to contain the [category] information.

meter-monitor segments ... page 44 line 26 ... contain meter information and/or monitor information, and the information of said segments causes subscriber station signal processor systems to assemble, record, and transmit meter records to remote billing stations and monitor records to remote ratings stations in fashions that are described [in many places of the disclosure, especially examples #3, #4 and #5.

...

... page 49 line 27 ... Examples of categories of [meter information and/or monitor] information include:

- meter instructions that instruct subscriber station meter apparatus to record particular meter-monitor segment information and maintain meter records of said information;

- origins of transmissions (eg., network source stations, broadcast stations, cable head end stations);

- dates and times;

- unique identifier codes for each program unit (including commercials);

- codes that identify uniquely each combining in a given combined medium program unit; codes that identify the subject matter of a program unit;

- unique codes for programming (other than programming identified by program unit codes) whose use obligates users to make payments (eg., royalties and residuals); and

- unique codes that identify the sources and suppliers of computer data.

For each category of information, a series of binary bits (hereinafter, a "field" or "meter-monitor field") exists in the meter-monitor segment to contain the information. In

any given category such as origins of transmissions, each distinct item such as each network source, broadcast, or cable head end station has a unique binary information code. In the preferred embodiment, the number of information bits in that category's meter-monitor field is the smallest number of bits capable of representing the binary value of the total number of distinct items. And the information code of each distinct item is within the range of binary numbers thus defined. In the preferred embodiment, date and time fields have sixteen bits.

Few commands require meter-monitor information of every information category. Often commands require no more than the identification codes of a specific combined medium program unit and of a specific combined medium combining within said program unit.

Because the amount of information in meter-monitor segments varies from command to command, in the preferred embodiment more than one format exists at any given time for meter-monitor segment information. ...

Because the number of categories of meter-monitor information varies from one command to the next, the length of meter-monitor segments varies. ...

In the preferred embodiment, each instance of a meter-monitor segment includes a format field that contains information that specifies the particular format of the meter-monitor segment of said instance. Within said field is a particular group of binary information bits (hereinafter, the "length token") that identifies the number of bits in a meter-monitor segment of said format. ...

In the preferred embodiment, each distinct meter-monitor segment format (including each distinct field format) also has a unique binary information code. ...

...

In the preferred embodiment, the bits of the length token are the first bits in each meter-monitor segment. ...

"MMS" ... page 104 line 7 ... (Hereinafter, the exact number of bits in any given meter-monitor segment is called, "MMS".)

"MMS-L" ... page 103 line 29 ... (Hereinafter, the number of the particular selected bit-length-number alternative associated with any given length token is called "MMS-L" to signify that said number is L bits less than the number bits in the meter- monitor segment in which said length token occurs.)

"MOVE bit" ... page 64 line 1 ... see "EOFS bit"

N

"normal transmission location" ... page 86 line 12 ... (Hereinafter, the preferred normal location for transmitting signals in any given communication medium is called, the "normal transmission location".)

"null outputs" ... page 159 line 10 ... Among such other outputs is one or more (hereinafter called, "null outputs") with capacity for accepting binary information and merely recording said information at particular memory associated with matrix switch, 39I, thereby overwriting and obliterating information previously recorded at said memory. The purpose of such a null output is to provide means whereby said switch can automatically cause information of any selected SPAM message to be discarded rather than transferred to addressed apparatus.

O

"original transmission stations" ... page 40 line 31 ... (Hereinafter, stations that originate broadcast transmissions are called "original transmission stations," ...

P

"padding bits" ... page 55 line 22 ... particular bits are added at the end of any command that is not already a multiple of the particular signal word bit length that applies in signal processor system communications at the subscriber stations to which said transmission is transmitted. (Hereinafter, said bits are called "padding bits.") Padding bits communicate no command information nor are padding bits part of any information segment. The sole purpose of padding bits is to render the information of any given SPAM command into a bit length that is, by itself, complete for signal processor system communication. Padding bits are added to command information prior to the transmission of said information at said station, and all subscriber station apparatus are preprogrammed to process padding bits. The particular number of padding bits that are added to any given command is the smallest number of bits required to render the bit length of said command into a multiple of said signal word bit length.

"pre-transmission evaluation" ... page 65 line 29 ... To prevent such erroneous processing, in the preferred embodiment, after the initial generation of any given instance of SPAM message information (not including end of file signal information) and before the embedding and transmitting of said instance, said information is transmitted through an apparatus, called an "EOFS valve," that detects end of file signals and is described below. If said valve detects in said information particular information that constitutes an end of file signal, before being embedded and transmitted, the binary information of said instance is rewritten, in a fashion well known in the art that may be manual, to cause substantively the same information processing at subscriber stations without containing an instance of information that is identical to the information of an end of file signal. (Hereinafter, such pre-transmission processing of a message is called a "pre-transmission evaluation.")

- "program instruction set" ... page 24 line 16 ... a ... set of [processing] instructions [conveyed in the information segment of a SPAM message] that is loaded and run [at receiver station (including ITS) computing apparatus] ... [at page 42 line 2, the meaning of "program instruction sets" is further defined as ->] (Hereinafter, instances of computer program information that cause ultimate receiver station apparatus to generate and display user specific information are called "program instruction sets.") ... [see also "intermediate generation set"]
- "program instruction set of Q" ... page 365 line 18 ... (Hereinafter, the program instruction set generated in example #9, under control of said intermediate generation set of Q, is called the "program instruction set of Q".)
- "program instruction set of Q.1" ... page 378 line 23 ... (Hereinafter, the program instruction set generated at the station of Fig. 6 in example #10 is called the "program instruction set of Q.1", signifying that said set is one version of complete program instruction set information of said instance of the network transmission of Q.)
- "program instruction set of Q.2" ... page 380 line 20 ... [Hereinafter, the program instruction set generated at said second station is called the "program instruction set of Q.2", signifying that said set is a second version of complete program instruction set information of said instance of the network transmission of Q.]
- "program originating studio" ... page 20 line 29 ... (Hereinafter, a studio or station that originates the broadcast transmission of programming is called the "program originating studio".)
- "program unit identification code" ... page 90 line 1 ... (Hereinafter, meter-monitor information that identifies the program unit of a given program may also be called the "program unit identification code".)
- "programming" ... page 11 line 7 ... The term "programming" refers to everything that is transmitted electronically to entertain, instruct or inform, including television, radio, broadcast print, and computer programming as well as combined medium programming.
- "pseudo command" ... page 48 line 31 ... The preferred embodiment includes one appropriate command (hereinafter called the "pseudo command") that is addressed to no apparatus ... [This command is] always transmitted with meter-monitor segment data that receiver station apparatus automatically process and record. By transmitting pseudo command ... signals, transmission stations cause receiver station apparatus to record meter-monitor segment information without executing controlled functions. The pseudo command enables a so-called ratings service to use the same system for gathering ratings on conventional programming transmissions that it uses for combined media without causing combined media apparatus to execute controlled functions at inappropriate times (eg., combine overlays onto displays of conventional television programming).

second combining synch command ... page 89 line 3 ... Each example focuses on the processing of the three signal messages of the Fig. 1C combining. The information of said messages include three combining synch commands and one program instruction set.

...

... page 90 line 4 The second message is of the information associated with the second combining synch command. [See page 25 line 34 through page 26 line 8 of the specification as well as "combining synch command" above.] Said second command has a "00" header, an execution segment, and a meter-monitor segment of five fields and addresses URS microcomputers, 205. Said second command causes said computers, 205, to combine the Fig. 1A information of each microcomputer, 205, with the information of Fig. 1B and transmit the combined information to monitors, 202M. Each meter-monitor segment field of the second command contains information of one of the following:

- . the subject matter of said "Wall Street Week" program,
- . the program unit of said program,
- . the unique code of said overlay given said program unit information,
- . the minute of said transmission within a particular one month period, and
- . the format of said meter-monitor segment information.

segment ... page 44 line 4 ... Fig. 2E shows one example of the composition of signal information (excluding bit information required for error detection and correction). The information in

Fig. 2E commences with a header which is particular binary information that synchronizes all subscriber station apparatus in the analysis of the information pattern that follows.

Following said header are three segments: an execution segment, a meter-monitor segment, and an information segment. As Fig. 2E shows, the header and execution and meter-monitor segments constitute a command.

"signal processor" ... page 15 line 8 ... signal processing apparatus defined at page 15, line 8.

"signal processor alternative #1" ... page 34 line 1 ... For certain applications, one particular embodiment (hereinafter, "signal processor alternative #1") can be configured to receive only other inputs at buffer/comparator, 8, in which case said embodiment has no oscillator, 6; switch, 1; mixers, 2 and 3; or decoders, 30 or 40.

"signal processor alternative #2" ... page 34 line 6 ... For other particular applications, another particular embodiment (hereinafter, "signal processor alternative #2") can be configured to receive only inputs at buffer/comparator, 14, in which case said embodiment has only buffer/comparator, 14; recorder, 16; clock, 18; and the control device apparatus associated with controller, 20.

"signal records" ... page 31 line 34 ... Buffer/comparator, 14, receives signal information that is meter information and/or monitor information from controller, 12, and from other inputs; organizes said received information into meter records and/or monitor records (called, in aggregate, hereinafter, "signal records")

"signal unit" ... page 14 line 26 ... (The term "signal unit" hereinafter means one complete signal instruction or information message unit. Examples of signal units are a unique code identifying a programming unit, or a unique purchase order number identifying the proper use of a programming unit, or a general instruction identifying whether a programming unit is to be retransmitted immediately or recorded for delayed transmission. The term "signal word" hereinafter means ...

"signal word" ... page 14 line 32 ... The term "signal word" hereinafter means one full discrete appearance of a signal as embedded at one time in one location on a transmission. Examples of signal words are a string of one or more digital data bits encoded together on a single line of video or sequentially in audio. Such strings may or may not have predetermined data bits to identify the beginnings and ends of words. Signal words may contain parts of signal units, whole signal units, or groups of partial or whole signal units or combinations.)

signals ... page 40 line 17 ... The signals of the present invention are the modalities whereby stations that originate programming transmissions control the handling, generating, and displaying of programming at subscriber stations.

...

SPAM signals control and coordinate a wide variety of subscriber stations. Said stations include ... "local affiliate" broadcast stations that receive and retransmit single network transmissions; ... "cable system headends" that receive and retransmit multiple network and local broadcast station transmissions; and ... "media centers" in homes, offices, theaters, etc. where subscribers view programming.

...

... page 43 line 32 ... SPAM signals contain binary information of the sort well known in the art including bit information required for error correction using forward error correction techniques, well known in the art, in point to multi-point communications; request retransmission techniques, well known in the art, in point to point communications; and/or other error correction techniques, as appropriate.

Fig. 2E shows one example of the composition of signal information (excluding bit information required for error detection and correction). The information in Fig. 2E commences with a header which is particular binary information that synchronizes all subscriber station apparatus in the analysis of the information pattern that follows. Following said header are three segments: an execution segment, a meter-monitor segment, and an information segment. As Fig. 2E shows, the header and execution and meter-monitor segments constitute a command.

"SPAM" ... page 40 line 21 ... (The term, "SPAM," is used, hereinafter, to refer to signal processing apparatus and methods of the present invention.)

"specified condition commands" ... page 44 line 33 ... Particular commands (called, hereinafter, "specified condition commands") always contain meter-monitor segments. Said commands cause addressed apparatus to perform controlled functions only when specified conditions exist, and meter-monitor information of said commands specifies the conditions that must exist.

"standard control-invoking value" ... page 285 line 7 ... see "covert control-invoking value"

T

third combining synch command ... page 89 line 3 ... Each example focuses on the processing of the three signal messages of the Fig. 1C combining. The information of said messages include three combining synch commands and one program instruction set.

...

... page 90 line 28 The third message is of the information associated with the third combining synch command. [See page 26 line 33 through page 27 line 7 of the specification as well as "combining synch command" above.] Said third command has only a "10" header and an execution segment and addresses URS microcomputers, 205. Said command causes

said computers, 205, to cease combining and transmit only the received composite video transmission to monitors, 202M, and to continue processing in a predetermined fashion (which fashion may be determined by the aforementioned program instruction set).

"transparent commands ... page 267 line 34 ... All eight of said messages are commands. The 1st- and 3rd-new-program-message (#5) and the 1st-new-radio-program- message (#5) signals are addressed to microcomputer, 205. Each informs said microcomputer of new programming transmissions to which said microcomputer can tune appropriate station receiver and display apparatus in fashions described below. (Hereinafter said commands are called "guide commands" because they can guide station control apparatus to desired programming.) By contrast, the 1st-, 2nd-, and 3rd-old-program-message (#5) messages, the 2nd-new-program-message (#5), and the 1st-old-radio-program- message (#5) inform no station control apparatus of new programming transmissions because said commands are addressed to no apparatus; the execution segment of each is the aforementioned pseudo-command. (Hereinafter, each said signal is called a "transparent command" because no subscriber station control apparatus "sees" said signal.)
